always—the unaffected portion is that which is in immediate connexion with the blood supply. One must be careful, of course, to be sure that the lesion is innocent, but only now and then is there any room for doubt. Nevertheless on one occasion I removed in their entirety bilateral ovarian tumours (fibromata) which very closely resembled solid malignant tumours; and on another occasion I removed bilateral ovarian cystic multilocular tumours from a young woman, preserving a portion of one ovary. On histological examination some parts of the tumours were difficult to recognize as being of an innocent character. However, no further pathological developments have occurred, and the patient is menstruating normally, nearly a year later. It is possible, too, that she may some day conceive. I have excised even endometriomata from the ovaries of women, and pregnancy has subsequently occurred. In this connexion I would refer to the view, which influences many surgeons, that one ovary is sufficient for all the needs of a woman, and in a sense this is perfectly true. But, on the other hand, how often when one ovary has been removed because it was the seat of an innocent neoplasm, has the second ovary been removed at a later date for a similar condition! It has never come to my knowledge that a new growth has developed subsequently in any ovary I have resected. This might happen, it is clear; but such an event must be very rare, for if resection be properly performed, the region in which neoplasms most frequently arise is excised, as they tend to grow away from the hilum. So, too, with retention cysts, whether follicular or parovarian, careful technique will generally enable us to save a considerable part of the normal ovarian tissue. When it is not possible to resect an ovary satisfactorily a graft from it may usually be made. The technique of ovarian resection may be very simple or may require careful planning, for the blood supply must not be impaired. Suture, too, of the ovarian wound should be neatly performed and a turning-in stitch employed. It is useful, also, to cover the scar with the peritoneum of the mesosalpinx, and to support the tube and ovary by making use of the round ligament.

Ovarian Grafting.—I have published so much on this subject, and have so often given statistics of the results of a large number of cases,[8] that I do not propose to deal at great length with this important procedure. Up to April, 1928, I had performed the operation of ovarian grafting 210 times in women during the reproductive period of life. Here, again, to secure good results the most careful technique is required. The chief factors for success seem to be:

1. Homoplastic grafting—that is, using the patient's own ovarian tissues.
2. Obtaining and using active ovarian substance.
3. Cutting the material into connected fragments with a sharp knife, that rapid vascularization may be favoured. I employ a skin-grafting knife and cut the ovarian substance in criss-cross fashion on a rubber pad.
4. Putting the material so treated in a suitable place.

Ovarian grafting may be (*a*) extragenital, or (*b*) genital. In the latter case the ovarian tissue is placed in the wall of the uterus—presenting, or not, in the uterine cavity according to the conceptional needs of the case. When extragenital implantation is practised this should be in a dry but vascular area, such as between fibres of the rectus muscle. So far as results are concerned, I can only speak of those attending the methods I have practised and published. These, however, have been confirmed recently by Norris[25] of Philadelphia, who states that he has followed my technique in all its details. My own results show that of all cases in which menstruation has been possible this function has been mantained in over 70 per cent.—not always regularly, of course, but often so—and has continued for many years. I have a patient in whom the function has now persisted for so long as thirteen years and three months, and is still regular. Of those cases in which menstruation was not possible, owing to the removal of the uterus, no less than about 90 per cent. remained free from menopausal symptoms, after the first few months following implantation—that is, after the graft has become vascularized. In spite of such good results let me repeat what I said in a paper on ovarian grafting many years ago:

> "I wish to insist that this procedure be looked upon as a measure of necessity, which can never be weighed in the balance against the preservation of the natural connexions of the normal ovary."[8]

Ovarian Transposition.—By this procedure we imply the transposition of an ovary with its normal connexions to an unusual site in order that conception may be made possible. The chief indication for this is unavoidable removal of the tubes in a woman, during the reproductive period, in whom an ovary can be preserved with its vascular supply. The operation was first suggested by Estes,[19] and Tuffier.[27] The former excised a cornu of the uterus and fixed an ovary, presenting in the uterine cavity, over the aperture. Pregnancy subsequently occurred in 4 cases out of 27 whose after-history was obtained. Tuffier placed the ovary partly in the uterine cavity through an incision in the posterior wall. I have practised the latter procedure nine times; the after-histories of seven of these patients have been obtained. In none of these seven has pregnancy yet supervened; some of the operations, however, were recently performed. On the other hand, it may well be that when practicable Estes' operation is the better, and I intend to give it a trial when a suitable case presents itself. A second indication for ovarian transposition, which I have practised, is in the case of an ectopic pregnancy when conservation of the tube is desired, but, owing to the oozing of blood from the fimbriated end, seems impossible of consummation. In these circumstances the slight pressure of an ovary placed in the lumen of the tube with the fimbriated end closed round it may enable a functional result to be secured. The technique of transposition of the ovary is, however, in its infancy, and we are still seeking the simplest and most effectual methods.

CONSERVATIVE OPERATIONS ON THE TUBES

Salpingotomy.—This was advocated for acute suppurative salpingitis first, I believe, by Holden in America, and subsequently practised by Bourne [13] and others in this country. The method of dealing with acute infections has not, however, received much support, probably because after the rude awakening, in the form of a high mortality rate, that came to many gynaecologists who formerly operated on salpingitis during the acute phases, the greater security afforded by operations conducted in the chronic stage, when the infecting organisms are dead, is not likely to be lightly cast aside.

It is, on the other hand, curious that salpingotomy in tubal pregnancy has not become a method of choice in suitable cases. In 1922 I recorded[10] my first case in which this procedure was deliberately performed to remove a tubal mole, which measured 5.5 by 3.5 cm., and contained chorionic villi. Since that time I have practised this method in suitable circumstances—that is to say, in those cases in which tubal haemorrhage had been arrested naturally or could be controlled, and in which there were still products of conception in the lumen which could not be removed through the abdominal ostium. In view of the routine way in which tubes and even ovaries together with the tubes were formerly, and still are by many, removed in cases of tubal pregnancy, even in those cases in which complete tubal abortion has occurred, it is necessary to say that such eradicative procedures may be entirely unjustifiable. It is enough to evacuate from

the peritoneal cavity the blood clots and products of conception which have been aborted through the abdominal ostium of the tube, or to remove them by that route with sponge forceps, and to suspend the tube and ovary if tubal haemorrhage has ceased. If bleeding is still going on, it may be necessary to remove the tube, but I think it is worth while in these cases to incise the tube and understitch, if possible, the bleeding points. In some cases the ovary may be transposed into the lumen of the tube as already described. I cannot believe that in such circumstances oozing of blood would continue for long. If the case is of longer standing, and a mole has formed in the tube, this may readily be removed by salpingotomy and the tube subsequently sutured. In some cases of this character salpingostomy may also be performed. Curiously enough in two consecutive cases of ectopic pregnancy on which I operated recently—one old-standing, and one in the acute stage—I found that each patient had a haematosalpinx on the other side, apparently due to a tubal pregnancy a long time previously. I have seen this several times. It is perhaps not an unexpected finding, for we have all operated on cases of repeated ectopic pregnancy in the same patient, and at considerable intervals of time. In the last of the two cases mentioned above lipiodol was injected into the uterus a fortnight after operation—double salpingotomy and salpingostomy—and both were seen to be patent. It is possible that this patient will now conceive normally.

Salpingostomy.—This, as I have just said, may be performed in cases of ectopic pregnancy, but undoubtedly the chief indication is occlusion of the fimbriated extremity of the tube due to infection. It is, of course, useless to perform this operation alone when there is obstruction in the isthmial or intramural regions, for which resection may be required. For the most part, therefore, salpingostomy is indicated for occlusion of the fimbriated extremity caused by pelvic infections following appendicitis, by ascending infections of the streptococcus (puerperal infection), or by infections following pelvic operations. Gonococci, unless the attack be very mild and the organisms rapidly perish, damage the mucosa of the tubes so much that it is rare to see fimbrial occlusion only. Even when this does happen, and salpingostomy is successfully performed so far as patency is concerned, pregnancy is not very likely to follow owing to the damage done to the mucosa, although at the time there be no obstruction elsewhere. Besides, reinfection with reocclusion is not uncommon. It is most important that, when the lumen has been exposed in the first step of salpingostomy, the patency of the isthmial and intramural regions should be tested by means of air inflation from above, as I first advocated in 1917,[7] some years before transuterine inflation was suggested. The technique of this procedure is simple. A metal syringe with a fine nipple-like nozzle is taken and the nipple gently inserted into the lumen of the tube. Pressure is then slowly exerted on the piston. If the tube be occluded nearer the uterus the distal portion is greatly distended. When the air has passed quickly to the uterine cavity it may often be heard gurgling through the cervix, or if the uterus be nipped between the fingers it can be felt and heard escaping into the vagina. As with other conservative operations, salpingostomy, if it is to be successful, requires the greatest care in its performance. The chief points on which stress must be laid are:

1. *Absolute haemostasis.* If there be any blood in the neighbourhood of the new ostium it will subsequently be occluded.

2. Close connexion between the ovarian end of the opening and the ovary; in this way an ovarian fimbria is replaced.

3. Suspension of the tube and ovary to the round ligament to prevent the new ostium adhering to the peritoneum of the lateral wall of the pelvis.

In a limited number of cases of salpingostomy subsequently tested by air inflation or with lipiodol we have found patency in over 70 per cent.

Tubal Resection.—This operation is concerned with the removal of portions of the tube which cannot satisfactorily be conserved, with the maintenance of the tubal lumen. The following are the conditions for which I have performed the operation:

(*a*) Ectopic pregnancy, when it is occasionally necessary to excise an affected area, usually at the fimbriated extremity.

(*b*) Infections, when the lumen of the tube is obstructed at one spot, generally in the intramural portion.

(*c*) Congenital abnormalities. The only states of congenital origin of which I have had the experience are in the case of an impervious uterine horn to which a normal tube has been attached, and in the not very uncommon forms of local impermeability of the tube. This latter condition is seen in the isthmial part of the tube, which is represented by a convoluted hard cord in the mesosalpinx.

In cases of tubal resection I have never myself performed tubo-tubal junction—that is, anastomosis of a patent fimbrial portion to a pervious uterine segment. I have, however, in a certain number of cases, resected the whole or part of the isthmial portion, together with the intramural, and have implanted the outer moiety of the tube in the uterus with success. As I have indicated, success may be noted by the subsequent examination with *x* rays of intrauterine lipiodol injections. Here I may relate a very remarkable case of tubal conservation, accomplished, first, by resection of an impervious uterine horn and implantation of the left tube into the main uterine body, and at a later date by salpingotomy of right tube for ectopic pregnancy, with subsequent full-term pregnancy for the first time in the uterus. These events are recorded below under sections (1), (2), and (3).

Mrs. C., aged 22 years; married for one year and four months; had never been pregnant.

(1) Admitted on December 18th, 1925, to the Royal Infirmary, Liverpool, suffering with pain in the back and premenstrual and intramenstrual dysmenorrhoea, which had been present since menstruation commenced when the patient was 13 years of age. The menstrual cycle was 3-5/23-26. On examination the uterus was found to be retroverted and retroflexed; nothing else abnormal was detected. The uterus was replaced in the normal position and a test made to discover whether the retroversion and flexion were responsible for the symptoms by keeping the uterus in the normal position with a pessary. All symptoms except the intramenstrual dysmenorrhoea were relieved. So the pessary was removed and surgical procedures were advised in order that the uterus might be fixed in a normal position. On February 4th, 1926, I performed laparotomy. The uterus was found to be retroverted and retroflexed, and the left cornu of the fundus was seen to terminate in a small rudimentary horn, such as I have described elsewhere as being a cause of intrinsic intramenstrual dysmenorrhoea. Attached to the distal end was an apparently normal Fallopian tube, which, on intra-abdominal inflation, was shown to be patent as far as its insertion into the rudimentary horn. Air passed through the right tube into the uterus. The rudimentary horn was excised and the tube was implanted into the cornu of the uterus. A "sling" operation was then performed to keep the uterus forwards, and the appendix was removed. The patient made a smooth recovery. On February 26th, 1926, lipiodol was injected into the uterus, and both tubes were found to be patent.

(2) The patient was not seen again until December 9th, 1927, when she returned to the out-patient department. She stated she had been quite well until November 20th, 1927, when a menstrual period began, and that since then she had bled without cessation. There had been no amenorrhoea. On examination a right tubal swelling was found, an ectopic pregnancy diagnosed, and she was admitted to the wards. On December 15th I once more opened the abdomen. A little blood was seen in the pelvis. The right tube and ovary were adherent to bowel. The tube was distended in its isthmial portion and dark in colour. The ovary was enlarged (ca. 7 by 5 cm.) and cystic. The distended tube was incised and the contents with blood clot were removed. The mole measured 3.2 by 1.5 cm., and chorionic villi were found in it. The wound in the tube was sutured, and the lumina of both tubes were tested by air inflation and found to be

patent. The cyst in the right ovary was removed by partial resection of that organ. Sections showed the cyst to be follicular in nature. The tube and ovary were suspended. There was no deformity on the left side where the tube had been implanted at the previous operation. An uneventful recovery followed.

(3) On April 7th, 1930, the patient reported at the ante-natal clinic that she had had amenorrhoea since January 30th, 1930. She was found to be pregnant. The patient went to full term. There was a breech presentation, and she was delivered in the Royal Infirmary on October 18th, 1930. Mother and child did well.

Successful tubal resection is not an easy operation, and it must be perfectly performed mechanically if the desired end is to be obtained. The chief points in the technique that make for success are:

1. Exposure of the uterine cavity through the cornu, or by means of vertical bisection of the uterus, as advocated by Solomons.[24]

2. Division into two flaps of the uterine end of the tube to be implanted, and the suturing of the anterior to the anterior wall of the uterine cavity and the other to the posterior.

3. Avoidance of pressure on the intramural part of the implanted tube when suture of the uterus is performed.

4. The passage of catgut or silkworm gut through the whole length of the tube into the uterine cavity.

CONSERVATIVE OPERATIONS ON THE UTERUS

Congenital Anomalies.—I have already discussed the resection of imperforate uterine horns. In many cases, however, of bicornuate uterus it is found that the two horns are well developed and of approximately equal size. In a majority, no doubt, there is no symptom or difficulty, but in some there is severe dysmenorrhoea, and occasionally obstructed labour, due to the non-pregnant horn blocking the pelvis. I have myself seen such cases. Provided the horns are not too widely separated, as may sometimes occur, and there is only one cervix, it is possible, by excising the inner sides of the two horns sufficiently to expose the cavities to unite the two outer halves and to form one uterus. I have performed this operation several times; so, too, has Munro Kerr,[23] and he has reported pregnancy subsequently to this operation; and this, indeed, is to be expected after so simple a procedure. When the cervix is duplex the operation is not so simple, but it is possible to deal with such cases surgically if there be necessity. Congenital occlusions of the cervix and uterine diverticula should always be treated conservatively, for hysterectomy is rarely required.

Infections.—The body of the uterus, to a great degree, is protected from infection and the lesions resulting therefrom by the endometrium, which undergoes cyclical changes and replacement. Nevertheless, the cornua and neighbouring fundus uteri are usually involved in serious tubal infections, even when of gonorrhoeal origin. In the acute phases of such an infection it is possible to find round-cell infiltration of the muscle coat of the uterus in these regions.[6] No doubt this and the subsequent fibrotic changes of chronic infection are in part responsible for the menorrhagia which is so common a symptom. For this reason Beuttner of Geneva, and I myself independently a little later, devised an operation which I called acrohysterectomy[5 6]—meaning removal of the summit of the uterus. At the same time, and in one piece, the seriously damaged tubes—pyosalpinges—are removed with it, and also the ovaries, if it is impossible to retain them safely in their normal situation, and an ovarian graft is made. So long ago as 1925 I recorded the results of 127 cases of acrohysterectomy.[11] In 108 of these ovarian grafting was necessary, and in 68 per cent. menstruation subsequently occurred. Success, in that the symptoms were relieved and the menopause averted, was obtained in 90 per cent. of all the cases. It is perhaps necessary to emphasize the fact that this operation—indeed, in my opinion, all operations designed for the treatment of salpingitis—should not be performed until the condition has become chronic. I have discussed this matter more fully elsewhere.[9] My mortality rate for the above series of cases, which included those of puerperal (streptococcal) origin, was 2.6 per cent., whereas Beuttner's, for his first 40 cases, was 12.5 per cent. It appears probable, therefore, that he may have been less cautious in this respect than I have been. In most of the patients, in whom the organism has been the gonococcus, the cervix is badly infected, and it may be lacerated. To complete the treatment it is necessary in such circumstances to amputate the cervix. An essential point—not practised by Beuttner—is the covering of the stumps of the infundibulo-pelvic ligaments and the sutured uterine wound with a flap of peritoneum dissected free from the utero-vesical pouch; this prevents intestinal adhesions. Undoubtedly this combination of conservative operations to relieve severe cases of salpingitis with cervical and fundal infection of the uterus is most satisfactory, for menstruation is usually maintained to the comfort and happiness of the patient.

Neoplasms.—Conservative surgery in regard to neoplasms of the uterus concerns, of course, only those which are innocent in nature. From the dawn of gynaecology it is certain that uterine polyps, adenomatous and fibromyomatous, have been successfully treated by conservative measures—vaginal removal—but I shall not have time to say more about such tumours here, although there are many points of clinical and operative interest in connexion with them. Fibromyoma uteri, and endometriomata and endometriomyomata uteri, however, are so common, and so much attention is at the present time being paid to the conservative principles enunciated by Alexander and others in connexion with them, that I must occupy some time in discussing them. First, with regard to endometrioma of the uterus. This is usually seen as a diffuse growth in the wall of the uterus, nearly the whole of which may be involved. The symptoms associated with the condition are severe dysmenorrhoea and menorrhagia. In well-developed states of this lesion I do not believe it is possible to conserve the whole of the uterus satisfactorily; but it may be possible to save some endometrium, and there is no justification for the removal of healthy ovaries. The case is often different with fibromyoma and endometriofibromyoma. In certain patients it may be possible to remove the tumours and to conserve the uterus for menstruation and pregnancy; and in others to leave enough endometrium to enable menstruation to continue.

Before I consider the operation of enucleation of fibromyoma, let me discuss the question of partial hysterectomy with endometrial conservation. As I have said, the "clean sweep"—removal of ovaries, tubes, and uterus—has been practised, and was advocated so recently as 1927,[16] for fibromyomata uteri and for some infections as a routine procedure. This I believe to be unjustifiable, except in a few exceptional cases. As with infections, even where subtotal hysterectomy is required for fibromyomata, it is nearly always possible to conserve some endometrium. I have known a patient in whom a very small area of endometrium has been preserved to menstruate subsequently for as long as seventeen years, until the natural menopause. It seems, therefore, that as with a small portion of ovary, so a little endometrium will sometimes go a long way. When, therefore, it is necessary to perform hysterectomy in young women it is advisable to leave some endometrium.

Transperitoneal Myomectomy.—I now come to the important conservative operation which during the last few years has been ardently proclaimed by Bonney.[16 17] What is the history of transperitoneal myomectomy? It has been stated that Spencer Wells first performed it, by removing subperitoneal pedunculated fibromyomata, and that it was afterwards practised on the Continent by A. Martin and by Shroeder, but was abandoned by them owing to a mortality rate of over 30 per cent. In 1894 William Alexander of the Liverpool Southern Hospital reported to the North of England Obstetrical and Gynaecological Society a case of myomectomy.[3] When Alexander read his second paper on the subject in Liverpool in 1897,[1] Professor Wallace called attention to his own paper[25] on the evolution of the treatment of fibromyoma uteri, read at the British Medical Association meeting in 1896, and stated that he had practised enucleation for twenty years—that is, since 1877—in the gynaecological ward of the Liverpool Royal Infirmary. However, there is no doubt that at the discussion which followed the third contribution by Alexander, before the British Gynaecological Society in March, 1898,[2 3] his position as a pioneer of myomectomy was recognized, if not applauded, by his London audience,[5 18] for he was the first strong advocate of the method, and showed that it could be safely performed even in difficult cases. From one patient he had removed nearly thirty tumours, a photograph of which is reproduced in his paper.[3] Since that date the operation has been consistently practised in suitable cases in Liverpool and elsewhere; and from 1903 transperitoneal myomectomy has figured among my own operations for fibromyoma uteri. In 1900 Giles[20] reported a successful case. In 1918 Bonney[14] published a short paper advocating an increase in the practice of myomectomy; no statistics were given. In 1922 Giles[21] and Bonney[15] read papers at a meeting in London. Whereas Bonney's paper, with a record of 100 cases, was an appeal for myomectomy without proper reservations being made, so far as I can discover, in regard to age and other essential qualifications, Giles's paper, as I shall show, was far more cautious. In mentioning Mayo's paper of 1911,[24] Bonney[15] wrote: "W. Mayo, in 1911, also wrote a paper on the myomectomies performed at the Mayo Clinic, 157 in number, with one death, but as they had done a very large number of hysterectomies during the same time it is obvious that the cases were selected." What else should be expected of an experienced surgeon of sound judgement and common sense? Giles, with Mayo, did not limit himself to myomectomy; he recorded and compared 987 cases of hysterectomy for fibromyoma with 167 cases of myomectomy performed by himself during the same period. I do not think a more judicial statement than his could be made to-day. The indications and limitations of the operation are clearly defined, and the important comparison between hysterectomy and myomectomy, to which I have referred, is made.

The chief difficulty associated with the enucleation of intramural, and of some cervical, fibromyomata is the bleeding. Bonney places a special clamp around the round ligaments and cervix, and sponge forceps on the infundibulopelvic ligaments. Other forms of compression may be used. The closure of the cavities is always effected by suture. In Bonney's latest series[17] the after-histories of 210 patients were obtained. This is about half the total number of his cases. In this series, moreover, 42.8 per cent were over 41 years of age. Of 77 in whom pregnancy was desired and possible, 30 conceived. Caesarean section was an unusually prominent feature in the delivery of these. In 13 (nearly half) of the 30 women who conceived, the fibromyoma was single; in 17 there were multiple tumours, but in more than half of these the number did not exceed 8, and we are given no indication of their sizes and positions, so we must draw our own conclusions. The value of such statistics in regard to well-recognized operations is that we can discover how far and in what direction our procedures have been justified.

Indications for Myomectomy.—In certain cases the indications are so definite that no gynaecologist would be performing his duty if he did not practise myomectomy. I do not propose here to discuss those in which nothing but one-eyed enthusiasm would lead an operator to perform this operation when it is clear the full genital functions cannot be conserved; by this I mean both menstruation and conception. I cannot insist too strongly, however, that the sole advantage of transperitoneal myomectomy over partial hysterectomy lies in the possibility of conception, for, as I have shown, it is easy to leave enough endometrium for menstruation in the performance of supravaginal hysterectomy. We should not as gynaecologists with judgement, and conscious of our duty to our patients, be interested in the performance of surgical feats once the pioneer stage has been passed, especially when at best they may lead, in inexpert hands, to worse results than other methods so far as immediate and remote mortality is concerned. Hence it may be definitely stated there is no place for myomectomy after the menopause, unless, perhaps, it be for solitary and pedunculated tumours causing symptoms. There are, at the same time, very definite indications for this operation, as has long been recognized, in women under 40 years of age, and in exceptional circumstances a little older, who can bear children, but in such cases the tumour should be single, or there should not be more than a few. The hunting out of dozens and dozens of "seedlings," and excessive trauma of the uterus must unfit this organ for reproduction. These facts have long been recognized, and seem supported by all the figures at present available. The operation is, too, a simple performance in comparison with certain of the other conservative gynaecological procedures. The indications, then, are:

1. Acute degenerations in fibromyomata during pregnancy.
2. The tumour is single or there is a limited number only of fibromyomata in women under 40 years of age, unless the patient marry shortly after that age and wish to bear children. If a woman has already several children, unless the fibromyoma are few in number and there is no special difficulty, this operation is not indicated; panhysterectomy by the vaginal or abdominal route is preferable in order that the cervix, which may have been injured in parturition, may be removed.

The contraindications are:

1. Women about or after the menopause.
2. Associated tubal infection, or old haematosalpinges.
3. When excessive mutilation of the uterus will be produced by the operation.

I have dealt with transperitoneal myomectomy somewhat fully, for there is, I believe, a very great danger that this operation, which is most beneficial in certain cases, will again fall into disrepute if it be practised indiscriminately in cases in which conception is not possible or thereby is made impossible.

CONCLUSION

In conclusion, I would ask those practising gynaecological surgery always to think conservatively rather than eradicatively when operating on women in the reproduction period for non-malignant conditions, and to give a proper trial to all conservative procedures that are designed to preserve function: time alone will show which deserve perpetuation and what is the best technique for their performance. I would, last of all, commend to notice the following words of my friend Professor W. P.

Graves of Harvard University, spoken in 1927 at the British Congress of Obstetrics and Gynaecology[22]:

"Conservative surgery of the pelvis is one of the most important branches of all gynaecology, in that its proper performance requires great skill, expert judgement, and a thorough knowledge of pelvic pathology. Success depends, therefore, in a great measure on the individual capacity of the operator."

ACTIVATED (IRRADIATED) FLUORESCEIN IN THE TREATMENT OF CANCER

BY

S. MONCKTON COPEMAN, M.D., F.R.C.P., F.R.S.

EMERITUS LECTURER ON PUBLIC HEALTH, WESTMINSTER HOSPITAL

In a paper by Mr. Frank Coke, Dr. Gouldesbrough, and myself, published in the *Journal* in August, 1929,[1] we described a method of treatment, initiated about two years previously,[2] which had continued to afford satisfactory results in certain cases of cancer, some of so advanced a character that they had been regarded by the surgeons in charge as definitely inoperable. It consists of the use of a slightly alkaline solution of the sodium salt of fluorescein sprayed or painted widely over the surface of the growth and followed by the application of radium, or of a dosage of *x* rays of moderate penetration.

Internal Administration

In some instances this superficial use of fluorescein may suffice for the required purpose, but where the growths are somewhat more deeply seated, or where there is reason to suspect dissemination of the disease, the fluorescein is also given orally or intravenously. Owing to the extremely low toxicity of the fluorescein salt considerable quantities may be administered in one or other of these ways, an ordinary dose given by the mouth consisting of two capsules of 7½ grains each (15 grains, or 1 gram in all). Mr. Stanford Cade, however, has reported to me an instance in which 1 drachm was administered, by mistake, in place of the 1 gram ordered—fortunately without the supervention of any unpleasant symptoms. In a few cases, however, the oral method has caused a feeling of sickness, when it has therefore been discontinued in favour of the intravenous route. The drug is gradually eliminated by the kidneys, its presence in the urine being demonstrable within about an hour after the administration.

The object of giving the fluorescein internally is to bring under its influence, on irradiation, outlying cells which may have become affected, or an organ like the liver, which may be suspected of harbouring secondary deposits, even though no clinical evidence of the fact may be apparent. Our more recent experience has, indeed, afforded reason for the hope that by giving the fluorescein internally as well as by local application to the skin, together with appropriate distribution of the subsequent irradiation, this technique may prove successful in preventing recurrence, not only locally, but generally. For intravenous inoculation 20 c.cm. of a sterilized 5 per cent. solution of sodium fluorescein should be slowly injected. The rapid diffusion of the drug, when given intravenously, may be manifested within a few minutes after the injection by a yellow coloration of the skin, although in comparatively dark-skinned individuals this effect may not be marked.

Activity of *X* Rays or Radium Increased by Fluorescein

In the correspondence which ensued on publication of our former paper in the *Journal*, reiterated stress was laid on a criticism to the effect that no evidence was available to prove that when successful results were obtained following on treatment with activated fluorescein, these might not equally have been obtained by the use of *x* rays or of radium alone. It may be well, therefore, to point out that evidence is now available which appears to have definitely disposed of the suggestion that equally good results can be produced without concomitant application of fluorescein. As a matter of fact, details of three cases giving information on this question were reported in the paper referred to, and a set of photographs (to which we specifically directed attention) was published about nine months previously.[3]

Lately, Mr. Stanford Cade informed me that he has now treated eight additional cases of breast cancer with radium and fluorescein. He added that, though difficult of decisive proof, he was definitely of opinion that the action of the radium had been reinforced by the simultaneous use of fluorescein. He promised full clinical details at a subsequent date.

More recently further cases have been brought to our notice, in which successful results have been obtained after previous failure with *x* rays alone. Reference to one of these is to be found in the annual report for 1928-29 of the medical superintendent of the North Middlesex Hospital. He states, on page 20, that "recently one remarkable case which had proved refractory to *x*-ray treatment, a large rodent ulcer of the face, healed up in a remarkably short time" as the outcome of the additional use of fluorescein.

A similar sequence of events is reported (August 20th, 1930) by Dr. H. M. Cutler, who, writing from Sydney, Australia, of his experience of the use of activated fluorescein in the treatment of malignant disease, says, *inter alia*: "With reference to the treatment of superficial conditions we cannot speak too highly. . . ." He adds that the response of rodent ulcers to radiation, when a preliminary painting with fluorescein is undertaken, is more marked than in the cases where no such painting is done, and instances a case of rodent ulcer involving the cartilage of the nose, recurrent after previous *x*-ray treatment, which, when treated with fluorescein irradiated

with a two-thirds B dose applied through a 1 mm. aluminium screen, "completely healed in three weeks, and has not recurred after about one year."

In this connexion, also, reference may be made to another case of severe recurrent carcinoma of the breast, ulcerated so deeply as to have almost destroyed the cartilages of three of the underlying ribs. To Dr. R. Mather Cordiner, assistant radiologist to St. George's Hospital, I am indebted for a personal description of the circumstances of this case, as also for a promise of further clinical details. The patient, handed over to him for treatment by Mr. Mower White, failed to show any response when, in the first instance, *x* rays alone were employed for the purpose. Accordingly, Dr. Cordiner turned to the use of activated fluorescein, and he informed me that he was greatly impressed by the fact that the deeply ulcerated area shortly commenced to close in from the bottom and sides, eventually healing up satisfactorily and completely.

FURTHER RESULTS OF FLUORESCEIN TREATMENT

Up to the present the number of cases treated successfully is not large, for the reasons: (1) that not having access to clinical material of my own, I have necessarily been dependent on the courtesy of others for any patients that have been handed over for fluorescein treatment; (2) that cases, especially of breast cancer, are now rarely found in the wards of the various metropolitan infirmaries, with the exception of a few in which the patients are in the last stages of the disease, or are actually moribund; and (3) that the majority of the patients who have become available for treatment have either been previously untreated cases at an inoperable stage, or such as have relapsed after operation with or without the application of *x* rays and radium, or of a combination of these methods; cases, therefore, which might be regarded as unlikely to prove amenable to any further form of treatment.

Thanks to the interest mainly of personal friends, a few private patients have been submitted to treatment, but, as regards hospital cases, our own work has been confined almost entirely to patients attending the radiological department of the Royal Northern Hospital, where, through the provision of a small grant by the Ministry of Health, at the instigation of the Departmental Committee on Cancer, an extra part-time radiological assistant has been provided, to whom has been assigned the compilation and filing of clinical and radiological records of patients treated by the fluorescein method.

Royal Northern Hospital Records

Between September, 1927, when treatment with activated fluorescein of patients suffering from malignant disease was commenced at the Royal Northern Hospital, and November 30th, 1930, 120 cases were submitted to this form of therapy, and the results, year by year, are shown in the following table, abstracted from the records of the radiological department:

Year	Total Number Treated	Died	Apparently Recovered*
1927-28	22	4	3
1929	42	18	11
1930 (to Nov. 30th) ...	55	11	9
Totals	120	33	23

* Alive and well, November 30th, 1930.

In comparing the number of successful results with the total number treated, as set out in this table, it is, we think, desirable to stress the fact that many of our patients have only come under treatment when in a far advanced stage of the disease. On the other hand, we realize that the period of time which has elapsed since the date of discharge of those "apparently recovered," especially in the more recent cases, is obviously too short to permit, at present, of judgement as to the permanence of the results thus far obtained. Still, it is of interest to record the fact that one of our earliest patients, who suffered from a large fungating cancer of the male breast, is alive and well after an interval of more than three years from the date of his admission to hospital.

Of the cases previously reported as discharged "apparently recovered," one patient, suffering from cancer of the breast, died on June 20th, 1930, after an interval of two and a half years from the date on which she was sent for fluorescein treatment to the radiological department by Mr. Mower White, who stated that the case was then quite inoperable. Of the remainder, the majority have been induced to come up for re-examination at intervals of about three months. These all apparently remain well, after an interval, in the earliest cases, extending to three and a half years (see Table, p. 660).

Reports as to further successful cases have also been received from Westminster Hospital, King's College Hospital, West Middlesex Hospital, North Middlesex Hospital, Paddington Hospital, St. Mary (Islington) Hospital, and the Norfolk and Norwich Hospital. Information has also been received from medical men in private practice as to a few cases of malignant disease in which all symptoms have disappeared as the outcome of treatment with activated flourescein, but owing to lack of space such clinical details as have come into our possession must be reserved for publication elsewhere.

INVESTIGATIONS OTHER THAN CLINICAL

During 1930, in addition to the considerable amount of time devoted mainly to clinical work with fluorescein and allied dyes,[4] we have carried out, with the help of other voluntary workers, to whom our best thanks are due, some preliminary investigations, chiefly from the chemical and physical side, and with special reference to the degree of fluorescence exhibited, on a number of compounds supplied to us by the dyestuffs department of Imperial Chemical Industries, Ltd., British Colloids, Ltd., Messrs. Boots, Ltd., and the Bayer Products, Ltd. —especially salts of the rhodamine group, and of the sodium salt of dichloroanthracene-disulphonic acid, to experiments with which we made brief reference in our paper.[4] With this latter salt—which, though practically colourless in a weak watery solution, exhibits on exposure to daylight or to screened ultra-violet rays an intense blue fluorescence, even when enormously diluted—experimental work on laboratory animals has been done by Dr. W. S. C. Copeman of St. Mary's Hospital, and by Dr. Goldby of King's College Hospital, with the object of determining the extent (if any) of the toxic action following on subcutaneous or intravenous injection. These experiments are not yet completed, as it is only recently that we have been able to obtain specially prepared samples of the drug in a satisfactorily pure state.

In addition, Dr. Herta Schwarbacher (also of King's College Hospital) has carried out an investigation as to any germicidal action possessed by the various salts under review. She reports that, whereas fluorescein is almost inert in this respect, the anthracene salt is definitely germicidal for *Staphylococcus albus*, although it is not nearly so efficient in this respect as phenol. I have since found that it possesses really remarkable deodorant properties when used (in 1 per cent. solution or even less) as a dressing for ulcerating malignant growths.

Some evidence, however, is already available indicating that, when irradiated, it is capable of exerting a selective lethal effect on malignant cells when activated by *x* rays

Tabular Statement as to Royal Northern Hospital Cases Discharged "Apparently Recovered"

Sex and Age	Admitted	Diagnosis	Condition when Admitted	Operation	Recurrence	Fluorescein Treatment Commenced	Discharged Recovered	Remarks
F., 68	21/7/28	Cancer of left breast	Fungating tumour. Pain, ulceration, and discharge; gland in axilla. Possibly operable, but patient refused consent	—	—	1/8 28	12/3 29	Well; gaining weight
M., 69	31/5/28	Cancer of *penis*	Ulceration of penis, and enlarged *glands in left groin*	2/5/28	Yes	31/5/28	10/9/29	Healed scar on penis No evidence of glands in groin
F., 60	-/3/28	Melanotic sarcoma of foot	Tumour on outer side of right foot. Deeply pigmented skin from external malleolus to sole	24/5 28, radium on 7.8 29	Yes	1/6/28 8/10.29	11/4/30	No sign of disease
F., 78	-/1/28	Cancer of left breast	Left breast much enlarged; hard immobile; ulceration of surface which had destroyed nipple	--	—	-/1/28	17.7/28	16 9/30: quite well
F., 57	2/3,28	Epithelioma of orbit	Growth in orbit	7/2 '28 (at Royal Westminster Ophthalmic Hospital) Incomplete	Yes	2/3/28	2/5 28	No sign of disease
F., 36	-/1 29	Cancer of vagina	Nodules round labia	Yes, ? date (in private nursing home)	Yes	-/1 29	15/10/29	No sign of disease
F., 62	22/8 29	Cancer of neck	Large growth beneath right jaw, and discharging sinuses above *clavicle*	Inoperable	—	22 8/29	23/1/30	2/9/30: no evidence of disease
F., 57	25/7/28	Cancer of breast	Recurrent nodules after operation	Yes	Yes	25/7/29	15/10/29	4/11/30: no sign of recurrence
M., 62	21/12/28	Lympho-sarcoma of forehead	Nodules on right side of face	—	—	21/12/28	9/1 29	No sign of disease
F., 45	28 8 29	Cancer of breast	Nodule on operation scar	Yes	Yes	29/8/29	14 4/30	Nodule had disappeared by 31/1/30
F., 59	1/6/27	Cancer of breast	Nodules along operation scar	10/6/27	Yes	12/12 28	23 1/30	20 6 30: no sign of disease
M., 43	9/10/24	Multiple sarcomata of skin	Recurrent nodules on skin of chest	Yes	Yes	29/10/28	12 3/30	13/2/30: Satisfactory result
F. (?)	—	Cancer of breast	—	Yes	—	18 10/28	30 5/29	16/10 30: no sign of disease
F., 55	—	Cancer of left breast	—	-/11/28	—	29/1 29	10/7 29	8/11/30: no sign of disease
F., 23	—	Sarcoma of right breast	—	Yes	Yes	—	14 12/29	31/10 30: Patient quite well
F., 44	—	Cancer of right breast	—	Yes	—	20/9 28	24/10 29	31/10 30: In excellent health; no recurrence
F., 41	—	Cancer of left breast	—	Yes	—	25 9 28	12 10.29	No sign of disease
F., 42	—	Cancer of right breast	—	Yes	—	—	3 11/30	Quite well
F., 39	—	Cancer of left breast	Enlarged glands in axilla	Yes	Yes	1/10/30	7 11/30	No glands in axilla or other sign of disease
F., 34	—	Cancer of breast	Recurrence in region of hip two years subsequent to operation	1928	Yes	30/10/30	30 12 30	No pain or other evidence of disease
F., 44	22 5/30	Cancer of breast	—	April, 1930	Yes	22 5/30	5 10 30	No sign of disease
F., 79	4/6/30	Multiple epitheliomata of face	—	4/6/30, lower right eyelid treated with radium (no improvement)	—	27/7/30	10/10 30	"Whole lesion has completely disappeared," leaving slight scarring
F., 74	17/3/30	Cancer of right breast (and glycosuria) operable	Stony-hard tumour, 4½ × 4 in., of right breast attached to skin, but not involving nipple. No glands in axilla	Refused	—	24 3/30	29 10/30	No sign of growth or recurrence. Discharge delayed for 14 days owing to superficial dermatitis, ? due to glycosuric condition

or radium, exceeding that exhibited by fluorescein, but we are not at present in a position to make any definite pronouncement on the subject.

Yet another experimental inquiry on which I have been engaged during the past few months, as time and opportunity have permitted, has been concerned with an attempt to obtain further evidence as to the relative lethal properties on embryonic cells, when irradiated, of fluorescein, isamine blue, and Na-dichloroanthracene-disulphonate through the effect produced on the growth of dwarf garden peas. Brief reference to the outcome of certain of these experiments in respect of the effect on growth of treatment with activated fluorescein may be found in a letter published in the *Journal* of October 25th, 1930 (p. 709). It is hoped to publish a complete account of the work at a later date.

Summary

With improved technique the use of activated fluorescein has now been found capable of affording excellent results in the treatment of certain cases of cancer, especially cancer of the breast, whether primary or when recurrent after operation or other treatment, as well as in malignant growths of a comparatively superficial character in other situations, including rodent ulcers. Successful results have also been obtained in cases which had previously failed to respond to irradiation methods alone, or had been considered to be inoperable.

Of cases of breast cancer, believed to be still in the "operable" stage, thus far only three have become available for treatment, which, in all three cases, has sufficed to bring about complete disappearance of the growth. None of these, as yet, has shown any signs of recurrence, although in one instance more than three years has now elapsed since treatment with activated fluorescein was undertaken.

That the results reported have been obtained without the necessity of any mutilating operation, coupled with the fact that the treatment causes no pain or discomfort to the patient, indicates the desirability of extended investigation of the possibilities and rationale of the method under more satisfactory conditions than has hitherto been feasible.

Thanks to the initiative of the Departmental Committee on Cancer of the Ministry of Health, an official communication has recently been forwarded to the Medical Research Council and to the British Empire Campaign, conveying a request that they, through their Joint Radiology Committee, would afford special facilities to this end.

TYPES OF PNEUMOCOCCI IN RELATION TO DISEASE

BY

J. T. SMEALL, *M.C.*, M.B., CH.B., D.P.H.

BACTERIOLOGY DEPARTMENT, ROYAL INFIRMARY, EDINBURGH

During the past two years over 150 strains of pneumococcus, isolated from lesions in different parts of the body, have been typed, as a matter of general interest. The results are shown in Table I.

TABLE I

Condition	Type I	Type II	Type III	Group IV	Total
Nasal catarrh, sinusitis, dacryocystitis	1	0	0	15	16
Meningitis	4	5	7	8	24
Otitis media, mastoiditis	2	1	4	7	14
Lobar pneumonia	12	35	0	13	60
Broncho-pneumonia...	3	3	2	1	9
Empyema thoracis	14	1	1	5	21
Endocarditis	1	0	0	2	3
Peritonitis	2	1	0	2	5
Miscellaneous, including pericarditis, arthritis, osteomyelitis, abscesses	2	2	1	1	6

In the pneumococci obtained from the eye, nose, and accessory sinuses the preponderance of Group IV organisms is in accordance with general experience. Whittle[1] has tested the virulence of strains isolated from such situations, and has found that they possess a low order of virulence and mostly belong to Group IV. The only type strain met with was one from a case of sphenoidal sinusitis. Spread of the infection from the sinus to the brain led to a fatal meningitis. A Type I pneumococcus was isolated from the cerebro-spinal fluid during life and from the brain and sphenoidal sinus by cultures made at necropsy.

MENINGITIS

Of 24 cases of meningitis investigated, 17 were dealt with during life by examination of the cerebro-spinal fluid and 7 after death by cultures from the brain. An analysis of the cases is given in Table II.

TABLE II.—*Meningitis*

Antecedent Condition	Type I	Type II	Type III	Group IV	Total
Otitis media and mastoiditis ...	0	0	6	2	8
Pneumonia	1	4	0	0	5
Fractured skull	1	0	0	3	4
Sinusitis	1	0	0	1	2
Osteomyelitis	0	0	1	0	1
Ulcerative endocarditis	0	1	0	0	1
Bronchiectasis	0	0	0	1	1
Unknown	1	0	0	1	2
Total	4	5	7	8	24

It will be seen that in a third of the cases the intracranial complication was due to spread of infection from the middle ear and mastoid. The results are noteworthy for the large proportion of Type III infections. As in the majority of cases the infecting organisms in middle-ear suppuration reach the ear by way of the Eustachian tube from the nasopharynx, we would expect that the implicated organisms would be present with a certain amount of frequency in the throats of normal people.

The incidence of pneumococci in the saliva and nasopharynx of healthy people has frequently been investigated in America. I have been unable, however, to trace any work on a big scale in this country with a view to determining the types normally present, though it seems to be accepted that the pneumococci of healthy mouths belong to the heterogeneous Group IV. On the other hand, in America it has been observed that while the Group IV organisms predominate, the presence of Type III strains is not at all uncommon. Thus Stillman,[2] in a series of 116 strains isolated from the mouths of normal individuals, found that 53.7 per cent. belonged to Group IV, while 27.6 per cent. were Type III organisms. Glynn and Digby of Liverpool[3] failed to find the Type III pneumococcus in twenty-five salivas examined ; all the ten strains isolated belonging to Group IV. By way of explanation of their absence they comment on the greater prevalence of Type III pneumonia in America as compared with that in this country. The prevalence of Type III organisms in cases of mastoiditis in the present series seems to suggest that they may occur in the normal British oropharynx with greater frequency than has so far been observed.

Comparison of the figures in Table III with one published in America is instructive.

TABLE III.—*Twenty-two Cases*

Lesion	Type I	Type II	Type III	Group IV
Otitis media and mastoiditis (see Table I)	2	1	4	7
Otitis media and mastoiditis with meningitis (see Table II)	0	0	6	2
	2	1	10	9

TABLE III(A).—*Pneumococcus Types in Acute Mastoiditis and Pneumococcal Meningitis, by John T. Bauer and Huston St. Clair,[4] Philadelphia. Thirteen Cases*

Lesion	Type I	Type II	Type III	Group IV
Otitis media and mastoiditis	2	0	6	0
Otitis media and mastoiditis with epidural abscess	0	0	1	0
Otitis media and mastoiditis with meningitis	0	0	2	2
	2	0	9	2

Both sets of figures show that of the type-specific strains Type III is that most commonly found in acute middle-ear and mastoid disease. In the cases under review the Type III infection showed a greater tendency to extend to the meninges.

In order to put pneumococcal infections of the middle ear and mastoid into their true perspective, it is perhaps not irrelevant to point out and to emphasize the fact that, while such infections are not uncommon, it is the streptococcus which is *facile princeps* in the role of infecting agent. That this is so may be readily seen from the following results obtained by routine examination of 120 swabs from the middle ear and mastoid submitted by the ear, nose, and throat department of the Royal Infirmary, Edinburgh.

TABLE IV.—*Acute Otitis Media and Mastoiditis*

Haemolytic streptococcus	73	90 or 75%
Other forms of streptococcus ..	17	
Pneumococcus		17 or 14.2%
Staphylococcus		11 or 9.2%
Diphtheroids		2 or 1.6%

Fisher (Ontario), in a series of 50 cases of acute otitis media or acute mastoiditis, found:

Haemolytic streptococcus	37 or 74%
Staphylococcus	8 or 16%
Pneumococcus	3 or 6%
No growth	2

Two of the pneumococci were Type III, and one Group IV.

By reference to Table II it will be seen that five of the meningitic cases occurred as complications of lobar pneumonia, one being Type I and four Type II. The predominance of Type II infections in this connexion is in accord with the type incidence in lobar pneumonia in Edinburgh at the present time.

Fracture of the skull was responsible for four of the cases. All the fractures were through the anterior fossa, with involvement of the orbit and some of the accessory sinuses. One pneumococcus was Type I, and three belonged to Group IV. This result is in keeping with the commoner occurrence of Group IV organisms in such situations. In face of gross trauma, these organisms (although of low virulence, as Whittle has observed) are unfortunately powerful enough to give the patient his quietus.

One interesting case of meningitis, following on a pneumococcal osteomyelitis of the spine, is worthy of mention because of its comparative rarity. A Type III pneumococcus was isolated from the cerebro-spinal fluid during life, and a similar organism was obtained from the pus surrounding the spine at the post-mortem examination, at which the pathologist found an osteomyelitis of the tenth dorsal and first lumbar vertebrae, together with a large psoas abscess.

All the twenty-four cases of meningitis were fatal. Some cases of recovery, however, have been recorded. For instance, Broadbent[5] states that he cured two cases occurring as a complication of pneumonia, despite the fact that in one of them the cerebro-spinal fluid resembled the pus of an empyema.

LOBAR PNEUMONIA

Sixty cases were examined, either by blood culture of sputum test during life, or by post-mortem cultures from the consolidated lung. The results were as follows:

Type I	Type II	Type III	Group IV
12, or 20%	35, or 58.3%	0	13, or 21.7%

The figures serve to show that Type II pneumococcus has been the chief causal agent in lobar pneumonia in Edinburgh during the past two years, and they support those recently published by Alston and Stewart.[6] They also prove that the type incidence in lobar pneumonia varies from time to time in the same locality, since five years ago the predominant type was Type I (Davidson and McLachlan). Statistics from Manchester, Liverpool, and Cambridge all show a prevalence of Type I infections in these areas. In connexion with this variation in type incidence, Armstrong is of opinion that Type II infections may become for a time very prevalent and then almost disappear, whereas Type I is the common and persistent type, and is especially concerned in producing the more severe forms of the disease

As a rule, in our cases, the pneumococcus was isolated from the lung at necropsy without much difficulty. The culture obtained was sometimes pure, but often contaminating organisms were present, such as *B. coli* and occasionally a streptococcus. On two occasions a streptococcus only was isolated, no pneumococcus being found. No Type III lobar pneumonia was encountered. In passing, it may be mentioned that in one case a pure growth of Friedländer's bacillus was obtained. The patient gave a history of having been gassed with "mustard gas" during the war, and since then he had had a chronic cough, with much thick, green, evil-smelling sputum.

BRONCHO-PNEUMONIA

Specimens from nine cases only were examined. In contrast to their absence in lobar pneumonia, two cases of Type III infection were met with. One case of broncho-pneumonia deserves special mention. It occurred during the pregnancy of an unmarried girl of 16, and caused the premature birth of an eight months' foetus. The question arose as to which was the primary infection—the pulmonary or the uterine. As there were signs of lung consolidation on admission to the infirmary, and no outward evidence of uterine infection, it was thought that the pulmonary condition was the more likely to be the primary one, the uterus being subsequently infected by the blood stream. A Type II pneumococcus was isolated from the sputum; a similar type was obtained along with *B. coli* from the uterus after death, while a Type II organism was also got from the meninges. The pathologist found a confluent broncho-pneumonia, a septic endometritis, and an early meningitis.

EMPYEMA

Twenty-one cases of empyema were examined, fourteen being Type I, or 66.6 per cent.; one Type II, or 4.8 per cent.; one Type III, or 4.8 per cent.; and five Group IV, or 23.8 per cent. The outstanding feature is the marked preponderance of Type I infections.

In a series of thirty-one cases, Whittle found 77.4 per cent. belonging to Type I. Certain combined British and American figures, quoted by Glynn and Digby, bring out the high incidence of Type I and Group IV infections, and the low incidence of Type II. Remembering that the Type II pneumococcus is the most prevalent organism here so far as pneumonia is concerned, the frequency of Type I empyemata is all the more noteworthy. It seems to demonstrate the superior invasive power of the Type I organism. Of twelve cases occurring as a complication of pneumonia, eight were Type I, or 66.6 per cent.; of these four, or 50 per cent., ended in death. The Types II and III cases recovered, while all the Group IV cases were fatal.

To account for the high mortality in the Group IV infections, it may be mentioned that two of them were mixed infections, one being combined with Pfeiffer's bacillus and the other with *Staphylococcus aureus*. Another case was associated with acute pericarditis.

ENDOCARDITIS

Vegetations from the heart valves were examined on twelve occasions. A non-haemolytic streptococcus was obtained from six of the cases and a pneumococcus from three. Attempts to isolate the infecting agent in the other three cases were foiled by the overgrowth of Gram-negative contaminating organisms. One of the pneumococci was Type I, and two belonged to Group IV.

The Type I case was interesting in that no pneumococcus was isolated from the consolidated lung, only a haemolytic streptococcus and Pfeiffer's bacillus being obtained.

OTHER DISEASES

Peritonitis.—Of the five cases investigated, one accompanied a pneumonia, one was a spread from a septic endometritis following an incomplete abortion, while another followed a tubo-ovarian abscess.

Arthritis.—A purulent arthritis of the ankle-joint was met with. It yielded a pneumococcus corresponding in type to that isolated from the lung.

Abscesses.—Subcutaneous abscesses have been described as concomitants of pneumonia. One case was encountered. From an abscess in the arm a type of pneumococcus was obtained similar to that isolated from the sputum. Two other and rarer kinds of abscesses were investigated. They were gluteal abscesses occurring at the site of injection of quinine-urea, used in the routine treatment of pneumonia. A pneumococcus was isolated in both instances. Unfortunately, in one case it was not typed. In the other, however, a type was secured which tallied with that previously isolated from the sputum. Perhaps some mishap at the time of the injection had permitted the quinine to devitalize the tissues, and so allowed the blood-borne organisms to settle there. The abscess, in the case that was typed, gave rise to a pyrexia, which subsided on evacuation of the pus.

SUMMARY

1. The pneumococcus most commonly found in the eye, nose, and accessory sinuses belongs to Group IV.

2. In acute otitis media and mastoiditis, Type III strains and Group IV organisms were found in about equal numbers. The type-specific strains showed a greater tendency to infect the meninges.

3. Attention is drawn to the important part that the streptococcus plays in acute middle-ear and mastoid disease. *Streptococcus pyogenes* was found in the majority of cases.

4. The most prevalent type of pneumococcus in cases of lobar pneumonia was found to be Type II.

5. In cases of empyema due to pneumococci, Type I strain was present in a large percentage.

The type serum used in this investigation was obtained from Dr. Wadsworth and Miss Kirkbride, of the Division of Laboratories and Research, Department of Health, State of New York, to whom I wish to express my indebtedness.

I take this opportunity of thanking Dr. Logan for his encouragement in compiling this paper.

BLACK HAIRY TONGUE*

BY

HUMPHREY H. GLEAVE, M.B., M.R.C.P.

LECTURER IN PATHOLOGY, UNIVERSITY OF LIVERPOOL

AND

SAMUEL HALLAM, L.D.S.

DENTAL SURGEON TO THE ROYAL INFIRMARY, LIVERPOOL

(From the Department of Pathology, University of Liverpool)

The condition known as hairy tongue appears to be more common in France than in England. General interest was first aroused by Raynaud in 1869, who likened the curious appearance to that of a field of corn laid low by the wind, a description which has struck successive observers as very appropriate. He also described the presence of numerous round bodies in the lesion, which he believed were fungus spores similar to those of ringworm. Much controversy took place among subsequent writers as to the relation of these spores to the disease, and it was established that though they were often present they were sometimes absent, as in the carefully described cases of Féréol. It was not until 1901 that Lucet identified these spores as yeast cells. He carefully investigated the yeast he obtained from a case, and it has since been known as *Cryptococcus linguae pilosae*. Attempts to transmit the condition failed. Dessois (1878) made inoculation experiments on his own tongue without success, and though "a sort of epidemic" of black tongue was seen in the Hospital for the Aged at Issy, Professor Chantemesse never succeeded, in numerous attempts, in transferring the condition to a healthy tongue.

A few cases have been recorded in England. R. Lake[1] of Barnes in 1891 had a typical case that showed the spores. The curious tongue described by Balfour-Graham,[2] in which the dorsum "looked exactly like the surface of a dog's nose," was probably of a different category, perhaps the result of mercurial treatment. Another case was described by Hunt and Leslie Roberts[3] at a meeting of the Liverpool Medical Institution in December, 1902. Other organisms have been suggested as a cause. Dinkler, in 1889, found the hairs covered with a Gram-positive filiform bacillus, as did Morelli in 1893. Guégan (1909) announced the discovery of a new species of oöspora, a fungus showing a mycelium composed of bacillary elements and bearing conidiophores and chlamydospores, which he believed, in symbiosis with the yeast of Lucet, was the causative organism. This organism is now classified in Brumpt's *Parasitologie* as an actinomyces. Weidman also isolated an organism which he believed was an actinomyces. Valuable recent observations are those of Catanei[4] (1928), who watched a case in a man, aged 80, for two years, and made four examinations of the hairs. On each occasion the yeast of Lucet was present, along with other moulds and bacteria, but none of these were pathogenic to animals, and inoculations into the healthy or scarified tongue of monkeys were without result. Charpy[5] attributed the disease to a nerve lesion, traumatic or functional, while Barnard[6] believed it was a disease of old people, and was an overgrowth of the filiform papillae due to the lack of normal rubbing of hard food. He states that he has known examination candidates mistake the condition for melanotic sarcoma. Heidingsfeld,[7] as a result of biopsy examinations, believed there were two forms of the disease—a spurious or evanescent, and a true or permanent, the latter dependent on a primary tendency to hyperkeratosis.

The nature of the pigment in these cases is uncertain, and we regret we did not investigate it fully in the case reported below. The prussian blue reaction for iron was negative. According to other observers it is insoluble in acids and alkalis, and bleaches in the mouth on treatment with hydrogen peroxide, but in our case a treatment on the spot with peroxide had no effect. Pigment-forming moulds have been reported in the lesion from time to time, but not with sufficient constancy to be considered an etiological factor. The yeasts of Lucet and Green are described as producing a certain amount of brown discoloration of the media, but in our case this did not take place.

The hairs are filaments of more or less keratinized epithelium attached to the summits of the filiform papillae. We consider the condition is probably a great exaggeration of the thick fur often seen in disease. An acid reaction of the mouth seems to be the essential underlying factor, whether produced by excess of fermentable food, gastritis, or paucity of saliva in the aged. The acid

* Read at a meeting of the Liverpool Medical Institution.

reaction favours the growth of yeasts and filiform acidophilous bacilli, and adhesion of the epithelial scales to each other. Once the condition begins the organisms are protected in the crypts between the filiform papillae, and by their fermentative power help to maintain the acidity of the mouth.

The case we report below yielded readily to a liquor potassae mouth wash. In other cases the lesion is said to disappear and recur in spite of treatment. In our view the essential treatment is to maintain an alkaline reaction in the mouth.

The patient was a man of 45, who had discovered a lesion on his tongue ten weeks before coming under observation. His tongue showed a triangular black hairy patch, the base at the circumvallate papillae and the sides a little distance from the margin and tip of the tongue. The hairs could be pushed in various directions with a spatula, but brisk scraping was necessary to remove them. They were longest at the centre and back of the lesion, where they measured up to three-quarters of an inch in length. The hairs were elastic, and stretched on attempting to pull them out. When removed the black colour was seen to occupy only the upper half of the hair, the remainder being white.

The patient was edentulous, but had good plates. He complained of a burning sensation over the tongue. He had rubbed off the growth once, and also stopped a bismuth mixture which he was taking for indigestion, without effect. After making the examination the growth was again briskly scraped away, and a liquor potassae and carbolic mouth wash prescribed. The patient reported that the lesion became gelatinous, and he scraped it away easily, so that it had disappeared a week later.

Pathological Findings.—Microscopically the hairs were not true hairs, but were composed of elongated masses of epithelial cells and scales. The pigment appeared as a diffuse brown coloration of the cells. The epithelial masses were covered on all sides with an enormous number of yeast cells, along with a Gram-positive filiform bacillus. Aerobic and anaerobic cultures on agar and 2 per cent. dextrose agar gave a growth of a few sarcinae and streptococci and very numerous colonies of a yeast and of a bacillus. The latter was finally identified as an acidophilus bacillus. It was non-pathogenic to guinea-pigs and rabbits. The yeast grew readily on dextrose agar, forming a white growth with no late pigment formation. Microscopically it showed round or oval forms, with sausage-shaped cells in some fluid media. Repeated tests for ascospore formation by placing an actively growing culture on plaster-of-Paris blocks standing in distilled water were negative, nor were ascospores seen in old cultures on carrot, potato, etc. In this respect it is identical with the yeasts obtained from cases of hairy tongue by Lucet, Guégan, and Green.[8] It produced acid and gas in dextrose, saccharose, and levulose, but had no effect on maltose, mannite, or lactose. These fermentation reactions are identical with those obtained by Lucet and Guégan. The pathogenicity of the yeast for laboratory animals was as follows. Doses up to 2 c.cm. of a saline suspension (strength 550 million per 1 c.cm.) given intraperitoneally to guinea-pigs (five experiments) or subcutaneously (three experiments) caused a local suppuration which healed readily and did not cause a generalized infection. Tested on two mice and two rats 0.5 c.cm. of this emulsion, given subcutaneously, was without effect. Three rabbits received intravenous injections of 0.5, 1.5, and 2 c.cm. respectively, and all survived.

Comment on Pathological Findings

From the morphology the yeast must be classed as a cryptococcus. It may be noted that had ascospores been found the yeast would correspond with certain of the common saccharomyces used in industry for brewing beer, etc. Hansen has shown that yeasts may lose their power of ascospore formation permanently if cultivated at a temperature of 32° to 37° C., and it seems likely that this cryptococcus is a saccharomyces which, owing to a long stay in the mouth, has become asporogenic. Yeasts are common inhabitants of the mouth and skin. Greenbaum and Klauder found yeasts on the skin in thirty-nine out of 150 unselected cases. These were saccharomyces or cryptococcus, of the same types that they isolated from their cases of yeast dermatitis. An examination of swabs from the tongue in seventy patients chosen at random in the casualty department of the Liverpool Royal Infirmary revealed the presence of yeasts in thirty-two, of which five showed mycelium formation (monilia).

A CASE OF "BLACK TONGUE"

BY

H. MORTIMER WHARRY, F.R.C.S.

SURGEON FOR DISEASES OF THE THROAT, NOSE, AND EAR, BOLINGBROKE HOSPITAL

After seeing several ordinary, or minor, cases, it is sometimes useful to describe an extreme case, which may throw some further light on a subject usually dismissed by the textbooks in one or two paragraphs.

Report of Case

The patient, a man aged 52, living in comfortable circumstances, came to see me complaining of chronic irritation of the throat and a cough which caused him continual annoyance, although it was not very serious. He had had this for eighteen months, and had been told that it was due to septic teeth, several of which he had had removed, but without any amelioration of the symptoms.

On examination I found an extensive pale brown spongy mass occupying the posterior half of his tongue. I removed this growth with a pair of forceps, and it came away in several long strips, leaving the tongue underneath looking approximately normal to the naked eye. The strips of growth were placed in a white dish and dried rapidly, assuming a dark purple colour, which was in marked contrast to the previous pale brown of the appearance noted when upon the dorsum of the tongue.

A fresh piece of growth was sent to the Laboratories of Pathology and Public Health, where the membrane was reported to consist of a "budding yeast-like fungus" of the monilia type.

On culture the growth was extensive, and brown in colour, and the sugar reactions were those of the *Monilia macroglossia*, which is identical with the *Cryptococcus linguae pilosae* found in cases of black tongue.

Commentary

The following points emerge from consideration of this extensive and long-standing case:

1. Black tongue may spread over the posterior third of the tongue, and is not confined to localized patches anterior to the circumvallate papillae.

2. The dark colour is caused by the fungus, and not necessarily by any changes in the papillae of the tongue itself.

3. The disease may be of long standing, and yet not cause any hypertrophy of the papillae, either filiform or circumvallate.

4. The hypertrophy of the filiform papillae, so often noticed before, is probably due to continuous irritation of the tongue at one particular spot where the fungus has taken a firm hold.

5. The growth of the fungus is the primary condition, and may exist without any lingual hypertrophy.

FOUR BILIARY ANOMALIES: A PLEA FOR CHOLECYST-GASTROSTOMY

BY

E. W. M. HUBERT PHILLIPS, D.M., M.CH.OXON.
F.R.C.S.ED.
HONORARY SURGEON, PORT TALBOT GENERAL HOSPITAL

DONALD ISAAC, M.R.C.S., L.R.C.P.

AND

JAMES MACDONALD, M.B., CH.B.

The following four cases of biliary disorder seem not unworthy of record as curiosities, while each presents one or more features of clinical, therapeutic, pathological, or surgical interest. The first two, contemporaneous in the same nursing home, demonstrate extremes in gall-bladder dimensions.

A Diminutive Gall-Bladder

A farmer, formerly robust, was never well after phlegmonous tonsillitis in 1924. In August, 1929, he came into our care, gravely ill from pernicious anaemia, with advanced subacute combined degeneration of the cord. Vigorous treatment with liver, combined with arsenite of iron and hydrochloric acid, soon rendered feasible and successful an operation under novocain infiltration for a large left incarcerated scrotal hernia, and for a right hydrocele of generous proportions. The former was a menace, and both militated against his re-education in walking. A series of attacks of biliary colic began in May, 1930, of increasing frequency and severity, until the situation became intolerable; and his importunity overcame our reluctance to accept the operative risk. On operating through a Kocher incision, under ether-assisted infiltration anaesthesia, we found the liver, reduced to half its bulk, tucked high under the dome of the diaphragm, to which it was intimately bound by perihepatic adhesions defying mobilization. The gall-bladder, which was extricated with difficulty from its fibro-fatty shroud, was about three centimetres long, and of the width of a rather meagre appendix. Its lumen was charged with black grit, and contained one friable black pigment stone. The viscus was enucleated, and the cystic duct drained through a separate stab puncture. A complete and fairly rapid convalescence ensued, at first seriously interrupted by paralytic ileus, which fortunately proved tractable to anti-gas-gangrene serum.

This case not only exemplifies the modest size to which a gall-bladder may shrink, and the pathological association of the pure black pigment stone with haemolytic disorders, but it affords an instance of the value of liver therapy, even in the nerve manifestations of Addison's anaemia, and of the encouraging results, which, on the whole, outweigh the disappointments associated with the giving of anti-*B. welchii* serum in paralytic ileus.

A Large and "Pelvic" Gall-Bladder

A female, aged 38, married, was suddenly prostrated with lower abdominal pain, and frequent urgent micturition, following two days of mechanical difficulty with her corset. She had a history of two years' indigestion, so vague as to amount to little more than stomach consciousness. (After the operation she admitted that she *had* had one or two attacks mildly reminiscent of angina *pectoris*.) Her temperature was 100° F., and her pulse rate of 110 was full and bounding. The whole abdomen was too tender to attempt an accurate diagnosis. A large tense cystic swelling occupied the hypogastrium and right iliac fossa; there alone rigidity was present. Pelvic investigation revealed a *tender*, elastic, fluctuating tumour distending the recto-vaginal pouch. The elevated bladder yielded about eight ounces of residual urine. She collapsed on her way to the nursing home. On exploration through a *small* tentative gynaecological wound, a cystic mass reticulated with engorged veins was discovered in the pelvis, but with a taut and twisted attachment to the under surface of the *low-lying* liver. For the safer negotiation of a pedicle of such potentialities a Kocher incision was employed. The cyst, which was of the size and shape of a Rugby *football*, was attenuated, and proved to be a gangrenous gall-bladder, suspended by a twisted, elongated, and occluded cystic duct. The cystic duct had implicated the hepatic and *common* ducts, so that they occupied the upper reaches of the stem. The whole tumour was clothed in front by a flattened dependent prolongation of liver substance, comparable to a Riedel's lobe. The thin fluid content, bile-free, but iridescent with cholesterin, was evacuated. The detached mucous membrane was heavily cholesterosed, though no free calculi occupied either the ducts or gall-bladder. The gall-bladder and Riedel-like process were excised. Bleeding from the denuded bed was so profuse that deep sutures through the liver substance were needed to control it. Recovery was rapid, complete, and free from untoward incident.

Apart from its gigantic proportions, the clinical interest of this gall-bladder rests in its close resemblance to an ovarian cyst with torsion of the pedicle.

A Bifid Gall-Bladder, associated with Acute Pancreatitis

A colliery carpenter, aged 48, had recovered reasonably, but not well enough for work, from an operation for acute pancreatitis, which appeared to comprise drainage of the gall-bladder and pancreas. After an interval of nine months he suffered from distressing prurigo for a few weeks. Intense icterus then set in and he became bronzed, and wasted rapidly. While in this condition he was suddenly seized with severe epigastric pain, tenderness, and slight rigidity. There was marked tenderness in the left costo-vertebral angle, and, as there was suggestion of recurrent acute pancreatitis, he underwent immediate laparotomy, which was performed through a right paramedian incision. The abdominal cavity contained free, rather dark fluid. Fat necrosis was present, but not conspicuous. A rather small gall-bladder readily obtruded, but a much larger one lay buried in a forbidding mass of adhesions. The two communicated through a common ampulla opening into a single cystic duct. Ducts and gall-bladders contained floating agglomerations of cholesterin, but no formed calculi. The pancreas was bulky and unduly palpable, and its head was indurated. Neither diffuse nor focal necrosis had taken place, possibly because the interval between the onset of the acute pain and the operation was short. Cholecyst-gastrostomy was the chosen procedure, the larger and now mobilized gall-bladder being impressed for the anastomosis. A noteworthy feature in the convalescence was the absence of any but very slight vomiting. Recovery has been such that the patient boasts of a degree of vigour unknown to him for many years, and is regularly engaged upon exacting work. The smaller gall-bladder was too definite to be called merely a Hartmann's pouch.

A Double-Chambered Gall-Bladder

A female, aged 56, married, was admitted to hospital for a recrudescence of attacks of biliary colic occurring at short intervals. Two years previously she had had a similar series. A thickened, fleshy, and lustreless gall-bladder, *average in* size and shape, was delivered through a Kocher incision. Its contents consisted of bile, mucus in excess, and viscid fluid, together with two pigment-veneered, faceted cholesterin stones. Its cavity was partitioned by a thickened sphincter-like ring of elastic, but dilatable, muscular tissue into two compartments, the hiatus between them being lined by loosely attached mucous membrane, puckered radially. There was no apparent cholesterosis. The head of the pancreas was *nodular, and a little* indurated. The common duct felt like an atheromatous artery. Convalescence was as uneventful as *in* the case of an interim appendicectomy; while there was only slight post-anaesthetic vomiting after the operation of cholecyst-gastrostomy.

COMMENTARY

From our fortunate, though very limited, experience of the application of the general principle of which cholecyst-gastrostomy is the type, this operation seems one of decided and, we venture to believe, increasing appeal, the more so since physiology has dispelled the apprehension previously associated with bile in the stomach by establishing its habitual regurgitation through the pylorus. The persistent vomiting, of pessimistic prediction, does not appear to occur. Admittedly, technical difficulty may often be prohibitive; still, there remain occasions when

intravisceral drainage is a manœuvre almost as rapid of execution as external drainage. The anastomosis commends itself, therefore, in selected cases, as a valuable alternative to cholecystostomy, with its manifest disadvantages. In this connexion, it would seem especially worthy of trial in pancreatitis of varying grades, in view of the theory of its pathogenesis, which is founded on the work of Opie and of Archibald, and on the convincing researches of Bruce Dick.

Suitably modified to the occasion, the principle might well be applied in the case of biliary disorder with peptic ulcer in "an indifferent surgical risk." In such a case the inspiration to apply it came to one of us just too late to obviate the trauma of cholecystectomy followed by gastro-jejunostomy in a patient none too well equipped. The ulcer could easily have been excised and the gall-bladder joined to the margins of the stomach wound.

The operation is more readily performed through a Kocher approach, and is further facilitated by the use of Wilkie's duodeno-jejunostomy clamps.

The anastomosis operation has the merit of revocability, and might well become that of election when there is doubt of the viability of the common duct, or certainty of its occlusion, when measures for the relief of the obstruction are impracticable, or fraught with grave hazard.

UNUSUAL DISTRIBUTION AND MORPHOLOGICAL MODIFICATION OF COMEDO

BY

J. GOODWIN TOMKINSON, M.D.

VISITING PHYSICIAN, SKIN WARDS, AND MEDICAL OFFICER IN CHARGE, SKIN ELECTRICAL DEPARTMENT, WESTERN INFIRMARY, GLASGOW; McCALL ANDERSON MEMORIAL LECTURER, UNIVERSITY OF GLASGOW

Topographical and morphological variation in quite common skin diseases occasionally introduces an element of confusion in diagnoses which otherwise would present no difficulty. Until quite recently I little suspected that a condition so common and obvious as comedo might roughly simulate in distribution and colour the lesion of xanthoma palpebrarum.

A retired journeyman engineer, aged 72, sought relief, in October, 1930, at the skin department of the Western Infirmary, for an affection of the eyelids. He appeared to be well preserved for his years, exhibited a mild degree of acne rosacea, and was bald save for a fringe of hair, approximately three inches deep, laterally and posteriorly. He had been in the habit of occasionally taking a little alcohol, of smoking three ounces of tobacco a week, and of eating a fair amount of sugar. On taking his seat he gave the impression of being the subject of xanthoma palpebrarum, more particularly of the left upper eyelid. This impression, however, on closer inspection, was soon dispelled, the lesions proving to be comedones of atypical distribution and, in my experience, of unique shape.

He said that he had been accustomed to work in a very hot atmosphere—subject, however, to some temperature variation—and with a great deal of oil. He had perspired very freely, and blackheads had developed, especially round the lower eyelids. The blackheads had been removed from time to time. Later, about ten to twelve years ago, blackheads had appeared on the upper lids some of which had slowly increased in size, gradually become flattened and pale yellow in colour, but had caused no difficulty in the closing or opening of the eyes, and had never been treated.

On inspection the left upper eyelid, mainly anteriorly, showed flat, approximately circular plaques, raised slightly above the skin level, pale yellow in colour, with a more or less central black spot, and resistant to the touch. They were distributed mainly anteriorly, and some tended to project beyond the palpebral margin. The largest was about a quarter of an inch in diameter. The right upper eyelid was affected, but did not exhibit

Left upper eyelid shows modified flattened disc-like comedones, in one of which, near inner canthus, a central dark point is visible. Some project beyond the palpebral margin.

the same degree of modification. Comedones were present on both lower lids.

While I have seen comedo on the lower eyelid in more than one patient, I have never noticed it, save in this particular case, on the upper one, nor has one of my colleagues, an ophthalmologist of careful observation and long experience.

The morphological modification is of particular interest. Although working a good deal with oil, he had habitually washed his face with cold water. This ablution is practised by many in a careless, half-hearted manner, as may be demonstrated in the case of some town dwellers in large smoky industrial centres during foggy weather, where a "high-water mark" may sometimes be left in the orbital region. Assuming that the patient had washed in this perfunctory manner, and especially so with cold water, the follicles would tend to remain plugged with oil and particulate matter. Two factors would probably largely account for the peripheral increase and resulting disc-like shape of the lesions—namely, the underlying dense fibrous tissue of the tarsal plates, and the diurnal palpebral movements.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

SARCOMA OF THE LUNG

In view of the difficulties of diagnosis involved, the following case may be of interest.

G. B. A., of fair physical development and with a chest expansion of three inches, enlisted in the Army in 1916, at the age of 32. In 1917 he was accidentally burnt on the face and hands while on service. Three months later, while still in hospital, he had a "haemoptysis—right apex crepitations"; two months later, "bronchitis—feeling faint on exertion"; no other symptoms or signs. In 1919 he was pensioned on account of bronchitis—"coughing up blood-streaked phlegm; V.F. and V.R. plus at right apex." These conditions remained much the same until September 29th, 1925, when pulmonary tuberculosis was diagnosed, and there was "active infiltration of the upper lobes of both lungs." His expansion had become "poor," and "a few crepitations were heard at the apex." On March 11th, 1926, pulmonary tuberculosis was admitted by the Ministry. He continued to show very

little alteration in his condition, and in 1928 he was still expectorating "spit streaked with blood." In March, 1930, a rapid change for the worse began to set in. He became depressed and started to lose weight. His cough became more troublesome and was still blood-stained. Ultimately, in July, 1930, his mental condition became such that he was certified and admitted to a mental hospital, where he died on September 1st, 1930. No evidence of pulmonary tuberculosis was found at the post-mortem examination. Death was "due to a small-celled sarcoma of the upper lobe of the right lung, with great overgrowth of the fibrous tissue; lower lobe congested; middle lobe relatively healthy; Left lung congested and oedematous, bronchi thickened."

This man evidently died from a sarcoma of the lung. He said that he was "gassed" during the war, but did not go sick. If no necropsy had been performed the widow would have been given a pension, for there is no doubt that he died from the same disease as that for which he received his pension, and the history is continuous. Is this an isolated case? Have there been numerous cases of pulmonary neoplasm, following gassing, etc., on war service? The post-mortem examination showed evidence of fibrosis, but not of ordinary tuberculosis. There had never been a positive sputum. I have seen one other similar case in which a necropsy was not performed. It was an anomalous case of tuberculosis going suddenly and rapidly down-hill, when ordinary experience would have expected a much less rapid decline —in a gassed ex-service man too.

If any reader can throw more light upon this matter, and especially if anyone can give me assistance in support of the claim of the widow to the pension, to which, I believe, she is entitled, I shall be much obliged. I can send the full clinical reports of the case.

HOWARD E. COLLIER, M.C., M.B., Ch.B.

Redditch.

DISSECTING ANEURYSM OF CORONARY ARTERY IN A WOMAN AGED 42: RUPTURE

The case reported below is, I think, sufficiently rare, at any rate in a woman of 42, to merit publication.

Between 8 and 9 a.m., on November 12th, 1930, I was called to see a married woman, who had been very ill all the previous night. The history was that, soon after partaking of a good meal of fried fish and chip potatoes, obtained from a neighbouring fried fish and chips shop, and which the rest of her family had shared with her with no ill effect, she was suddenly seized with severe retching and vomiting, which persisted throughout the night.

On examination the pulse and temperature were normal; nothing was found in the abdomen, and nothing in the chest, other than a soft systolic murmur at the apex. Having satisfied myself that I was not dealing with an abdominal catastrophe, and that the cause of the trouble was "fried fish and chips," I prescribed 1 ounce of castor oil and a mixture of bismuth and soda, with 3 minims of dilute hydrocyanic acid for each dose; no food, and rest in bed.

At 3.15 a.m. on November 13th I received an urgent call to the patient's house because she had just died. On arrival, I gathered from her husband that during the day she had been feeling better, and she had not vomited so frequently, and had expressed a desire to get up. During the night, however, she had been restless and unable to sleep, and complained of pain in the chest, and nausea. At 3 o'clock she sat up in bed, and said she was going to vomit, and having retched once, suddenly fell back dead in her husband's arms.

On the afternoon of November 13th I made a post-mortem examination. In the abdomen I found nothing abnormal. On opening the pericardium, however, I was astonished to find it full of blood. The heart appeared normal, the muscles in good condition, and the valves were all normal. In the wall, however, there was a considerable area between the aorta and pulmonary artery, where there had been extensive haemorrhage, and on opening up the right coronary artery I found marked atheroma, with a dissecting aneurysm, which had evidently ruptured during the last sudden and violent retching attack. My findings were verified by my colleague Dr. J. Notley, to whom I am indebted for his assistance.

With regard to the patient's past history, I have known her many years. I attended her in her four confinements, and all her children are healthy and strong; she had had no miscarriages, and I have never had any reason to suspect any history of syphilis. Her father and mother both lived to the age of 70. Her father suffered from arterio-sclerosis, chronic bronchitis, and emphysema, and her mother from diabetes.

Kettering.

PERFORATIONS OF JEJUNUM

The following case seems worthy of publication in view of the age of the patient, the unusual situation of the perforations, and the failure of a technically perfect gastro-enterostomy to circumvent them.

From the age of 8½ years J. G. B. suffered from severe epigastric pain. In May, 1924, when he was 12½, Mr. S. T. Irwin saw him, and, after a confirmatory *x*-ray examination, diagnosed duodenal ulcer, and operated on him. Laparotomy revealed a large duodenal ulcer and a number of caseous mesenteric glands. A posterior no-loop gastro-enterostomy was done, and the appendix removed. Apart from occasional attacks of colic and nausea, he remained well until May, 1928, when he perforated. Mr. R. J. McConnell operated, and found a perforation of the jejunum just distal to the junction; he closed the perforation, and the boy made a good recovery. A subsequent *x*-ray examination showed slow emptying of the stomach and narrowing of the gastro-enterostomy opening.

Until October, 1930, the patient remained well, but took alkalis daily; then occasional attacks of pain, relieved by food, occurred. On December 21st he was seized with severe abdominal pain, and was seen by Dr. Wallace of Lavan, who diagnosed a perforation and asked me to see him. I opened his abdomen, and found a small perforation of the jejunum fully one-quarter of an inch proximal to the gastro-enterostomy opening, which itself showed no evidence of ulceration, admitted easily the tips of two fingers, and was normal in every way. The duodenum showed extensive scarring, but no sign of active ulceration; recovery was uninterrupted.

Reports of Societies

BULLOUS DERMATOSES

At a meeting of the London Association of the Medical Women's Federation, held on March 24th, with the president, Dr. LETITIA FAIRFIELD, in the chair, Dr. ELIZABETH HUNT read a paper on bullous dermatoses. Symptoms were so obtrusive in skin diseases, she said, that it was not surprising that the obvious lesions had been made the basis of classification, but the result was that nomenclature in dermatology was heavily overloaded. The bulla differed from the vesicle only in size, and both were signs of increased permeability of the vessel walls—a part of the defence mechanism of the skin. Whereas vesicles and bullae were all produced by the release of a histamine-like substance, bullae seemed to arise usually when the inflammatory reaction was intense, but sometimes they appeared on normal skin. The contained fluid was first clear, but became cloudy or even haemorrhagic. It contained albumin, fibrin strands, and cells in which eosinophils might predominate. When the bulla broke down it left a raw surface, but healing usually followed without scarring. The name pemphigus was now

restricted to acute, chronic, or true pemphigus, and foliaceous pemphigus and pemphigus vegetans.

Acute pemphigus was very rare; there was always a history of a wound, followed a few weeks later by an outbreak of bullae with high fever. The condition was fatal. No organism had been isolated. In chronic pemphigus the bullae appeared in crops without any inflammatory areola, and their fluid was sterile. They often occurred first in the mouth or conjunctiva. There was a sensation of tightness and burning with malaise and irregular pyrexia, but no pain save for that of conjunctivitis. Depression and insomnia followed, and the patient was liable to intercurrent disease. The treatment was empirical: to maintain the strength and mitigate the misery. Septic foci should be eliminated. Arsenic was the favourite drug, but in Dr. Hunt's cases quinine had proved better. A water bed and a skilled nurse were essential. The denuded areas exposed by coalescence of the bullae must be protected. Pemphigus foliaceus was very rare, and usually occurred in young women as a persistent eruption of flaccid bullae, which rapidly ruptured, causing a generalized exfoliative dermatitis, which healed slowly. The prognosis was very grave. The diagnosis of pemphigus depended on the bullous eruption, especially in the mouth and eye. In many other conditions bullae developed later, but were then mixed with other types of lesion.

Dr. Hunt described modern work on allergy, and went on to give an account of some allergic manifestations in which cutaneous reactions occurred. Bullae might cap the wheals of urticaria, of which the commonest cause was sensitization to a food, though psychical factors also played a part. The first step in treatment was to find the cause, and occasionally an injection of the patient's own proteose would succeed when all else failed. Sometimes a change of environment alone would cure the urticaria papulosa or lichen urticatus of infants, but attention to diet and small doses of grey powder were also valuable. Dermatitis herpetiformis was characterized by polymorphous lesions grouped like herpes and apt to recur. There was a marked eosinophilia, but the general health remained good. Herpes gestationis or hydroa gravidarum occurred after the tenth week of pregnancy, and might recur in a subsequent pregnancy. It was characterized by multiform lesions with much itching, and was extremely hard to treat. Arsenic, bromides, autohaemotherapy, ultra-violet light baths, and proteose injections might be useful. It was believed to be a toxaemia of pregnancy. Cheiropompholyx caused grouped vesicles and bullae on the palms and soles. It affected women much more than men, and was apt to recur, sometimes seasonally. It had to be distinguished from eczematoid ringworm, in which a fungus was found. All these conditions had certain features in common: subjective symptoms, particularly itching, and a psychical factor in the etiology. In some complex manner the vegetative nervous system seemed to be involved.

There were two bullous conditions of infective origin. The bullous syphilide of infants might be present at birth or appear any time after, but usually about the third week. Prognosis was bad, and the treatment was mercurial. It was doubtful whether erythema multiforme belonged here, as it might be produced by drugs. It was characterized by symmetrical rose-red lesions of different sizes and shapes, with much exudation. There was usually a rheumatic history, and the streptococcus could often be found in the tonsils. The condition had been regarded as a streptococcide, and often cleared up with rest, dieting, and salicylates. Bullous erythema multiforme was distinguished from dermatitis herpetiformis by the burning rather than itching sensation it caused. Erythema iris showed a central bulla with a target-like arrangement of concentric rings round it. Impetigo contagiosa was an inoculation of the skin by *Streptococcus pyogenes*, and must be diagnosed from the bullous syphilide and epidermolysis hereditaria bullosa, which was a congenital vulnerability of the skin, in which bullae were produced by blows and pressure. Finally, there were bullous eruptions produced artificially, usually by young women, sometimes obviously to gain sympathy, but sometimes the patients were quite callous. The palatal and conjunctival reflexes were absent in these cases, and areas of hyperaesthesia and analgesia could be found.

SURGERY OF THE PITUITARY BODY

A joint meeting of the Liverpool Medical Institution and the Manchester Medical Society was held at Liverpool on March 5th, when Mr. GEOFFREY JEFFERSON read a paper on the surgery of the pituitary body.

After referring to the two main groups of pituitary dysfunction, Mr. Jefferson spoke of those symptoms which were once regarded as of pituitary origin, but which now seem to be tuberal. Striking hypopituitary pictures might be induced by tumours at a distance, notably by those in the cerebellum with retention dilatation of the third ventricle and damage to the hypothalamus. Illustrative cases were described. The acromegalic group were no longer the most important clinically, since they represented the minority of pituitary enlargements. In this disease the glandular change was not a true tumour, but a hypertrophy with toxic secretion. The commoner chromophobe adenoma appeared to be a true tumour, and produced its effects by interfering with the normal pituitary secretions. Mr. Jefferson thought that too much attention was paid in teaching and discussion to the somatic effects of pituitary tumours. These required some time to develop, and an adenoma might become large enough to cause blindness by pressure on the optic nerves before gross signs of body change appeared. He thought this fact ought to be more widely known, because the diagnosis of pituitary tumour was often considerably delayed or missed altogether on account of the absence of those signs which the clinician had been taught to expect in pituitary lesions. He then showed photographs illustrating this point. It seemed to him that the most obvious pictures of hypopituitarism were given by persons who had no pituitary tumour at all. In these, infection or acute illness seemed to have damaged the gland. At all events it was unwise to diagnose tumour on somatic changes alone. This represented the corollary of what he had said of optic nerve pressure by adenomata. Mr. Jefferson then described cases of suprasellar meningioma and of chiasmal arachnoiditis. The diagnosis of pituitary tumour was generally not difficult, for the ophthalmoscope, perimeter, and *x* ray left one in little doubt, though atypical cases existed. At operation he was using the transfrontal route of Frazier and Sargent, but thought that for the moderate-sized cyst the transphenoidal route was safer. The difficulty was to know beforehand which was the better route for any given case. The risks of post-operative hyperthermia were certainly less by the nasal route, but it was an unsatisfactory approach for the more solid tumours.

SANOCRYSIN FOR PHTHISIS IN CHILDREN

Dr. H. T. ASHBY, in a paper on the treatment of pulmonary tuberculosis in children by sanocrysin, said that sanocrysin in the treatment of tuberculosis was first introduced by Moellgaard of Copenhagen in 1925. The initial results obtained in this country were not good, the drug being used either in unsuitable cases or in too large

doses. Now, however, it had a recognized place in the treatment of pulmonary tuberculosis, being most useful in the exudative type. Abdominal and renal tuberculosis were contraindications to treatment. The drug was made up in a 3 per cent. solution, and the initial dose was 0.01 gram. A course consisted of ten to twelve intramuscular injections, with a maximum dose of 0.5 gram. These doses were well tolerated, with improvement of symptoms and increase of weight in most of the cases treated. The chief dangers were diarrhoea and albuminuria. The results of treatment, even in severe cases, were encouraging.

CALCULUS OF THE URETER

Mr. J. B. MACALPINE discussed the diagnosis of ureteric calculi, showing lantern slides of selected cases. Large stones might be diagnosed by the *x* ray alone, but small ones must be confirmed by cystoscopic examination, as they might be invisible on account of smallness or permeability to the *x* rays, also because shadows adjacent to the ureter might cause confusion. Plates were shown in which an opaque bougie acted as a pointer, its tip abutting on, or passing close to, the stone. Re-exposure from a different angle or stereoscopy would clear up doubtful shadows. Pyelography, by outlining the ureter, showed that the shadow was contained within its lumen. Quoting another case Mr. Macalpine said that no calculus was found by direct radiography, but a pyelogram showed an area of diminished opacity within the shadow of the ureter, caused by a radiographically transparent calculus.

ANALGESIA IN LABOUR

At the last meeting of the Section of Obstetrics of the Royal Academy of Medicine in Ireland, held in Dublin at the Royal College of Physicians, a paper by Dr. O'DONEL BROWNE on Gwathmey anaesthesia in labour was read in his absence by the president, Dr. A. H. DAVIDSON.

The results of the treatment of forty-three cases according to the technique of Gwathmey and Harrar were described and compared with those obtained by the use of scopolamine-morphine. The routine treatment consisted of a hypodermic injection of 1/4 grain of morphine and 2 c.cm. of a 50 per cent. magnesium sulphate solution as soon as labour was definite in a multipara or the os was three fingers dilated in a primipara. Twenty minutes later another 2 c.cm. of magnesium sulphate was given. The ears were plugged, and as the analgesic effect of these drugs wore off, anaesthesia was induced with the rectal ether anaesthesia mixture, given slowly between the pains. This mixture consisted of 2½ oz. of anaesthetic ether, 20 grains of quinine alkaloid, 40 minims of absolute alcohol, and 2 oz. of olive oil. Twenty minutes later a further dose of 2 c.cm. of 50 per cent. magnesium sulphate was given intramuscularly. It was found that magnesium sulphate prolonged the action of the morphine without increasing its toxicity. Rectal ether instillations were repeated whenever necessary throughout labour. The labours progressed normally, and the co-operation of an analgesic patient assisted greatly when any manipulation was needed. One case of inertia was under anaesthesia for thirty-seven hours, with no ill effects to mother or child. No bowel complications were noted, and the puerperium showed no abnormality. No cases of asphyxia neonatorum occurred; thus the stages functioned satisfactorily, and lactation was easily established. There was one stillbirth due to prolapse of the cord, and one patient became morbid, due to mastitis. The results were that 97 per cent. of cases derived benefit, in agreement with Harrar's report. Both these reports found rectal ether 30 per cent. higher in efficiency than "twilight sleep," and without danger to the infant; 2 per cent. of patients treated were absolutely unaware of any pain from the first injection of morphine and magnesium sulphate. Dr. O'Donel Browne considered that this method of relieving pain during such a long space of time was far in advance of any other means in use at the present day; it was simple and safe, and effective in 97 per cent. of cases.

Dr. G. MELDON said that he found rectal ether an extremely satisfactory anaesthetic, but in patients who came into hospital early on the morning of operation, or on the previous evening, it was not so successful. He thought the reason for this was that the bowels were not properly cleared out. As a routine, he put a catheter into the rectum, gave the injection, and left the catheter in. He had never seen any rectal trouble occur following injections of rectal ether.

Dr. T. M. HEALY said that when Gwathmey's paper on anaesthesia in labour appeared in 1923 some cases had been treated in this manner at the Coombe Hospital according to Gwathmey's technique, but the results were rather disappointing. Since the stronger solutions of magnesium sulphate had been introduced in 1924, however, he had been more satisfied with the results obtained. Some patients had scopolamine-morphine anaesthesia in one labour and Gwathmey anaesthesia in another, and seemed to think that the quinine was less nauseating. Magnesium sulphate was now always given intramuscularly, though this was not done when the method was first started. He had seen no cases of difficulty in the third stage of labour, and no difference in the stillbirth rate since this method of anaesthesia had been used.

Dr. D. V. MORRIS said he had been using Gwathmey anaesthesia for some time, and in private practice regarded it as very successful. He was content if he got analgesia. In hospital cases such good results could not be expected as in private practice.

Dr. SOLOMONS, Master of the Rotunda, said that when he suggested that Dr. O'Donel Browne should study the Gwathmey method of anaesthesia in labour, he was anxious to find out if this was a method that could be of general use, not only to the specialist, but to the general practitioner. Dr. Browne had demonstrated certain very definite points, even though the number of cases was small. It was extremely difficult for the assistants at the Rotunda to devote a great deal of time to such cases. The routine work was heavy, and the isolation wards so necessary for such an investigation were not always available. He had given the results in forty-one cases, and, as there were approximately 6,000 confinements in the hospital in the time under review, it seemed to show that the method was not one for the busy general practitioner. In fact, in spite of the statements, and in spite of the excellent work of Gwathmey and his disciples, he did not see that this method would be any more universal than "twilight sleep." When he and his co-assistant, the late Dr. Freeland, were working on the subject of scopolamine-morphine narcosis about twenty years ago, experiments had to be made as to correct dosage, so that the results of the paper, written at that time, could scarcely be compared with the results obtained by the Gwathmey method, where the dosage was definite. He did not see much to choose between the methods—both had disadvantages and advantages. He believed that the ideal anaesthesia was gas and oxygen.

Dr. DAVIDSON said that the conclusions which Dr. O'Donel Browne had come to regarding Gwathmey anaesthesia seem to bury the bogy about quinine. He personally had never seen a case in which the giving of quinine had done any harm to the baby.

Reviews

THE BILE ACIDS

The physiology of the bile acids remains one of the outstanding problems of hepatic physiology, and so far progress in our knowledge of their origin, metabolism, and functions, has been poor indeed. L. CUNY has therefore performed a great service in collecting in monograph form an account of all the work done on the bile acids by chemists, physiologists, and clinicians. Much of the contents is chemical, and difficult for the ordinary man to comprehend, but for those specially interested a mine of information is at hand. It is good to see on page 47 a full reference to the "réaction de Hay," which was erroneously introduced into French literature, as Cuny admits, as the "*réaction de Haycraft.*" *On looking up* Cuny's enormous bibliography of 342 publications about bile acids, it is seen, however, that Hay's name is absent. This is scarcely to be wondered at, for unfortunately Professor Matthew Hay, then in Edinburgh and later in Aberdeen (where he resides), did not publish his method as a separate paper. For the sake of those interested in this subject it is worth while recalling that Matthew Hay's method of testing for bile acids in urine with flowers of sulphur was first described in Landois and Stirling's *Text Book of Human Physiology*, published in 1886.

All the methods or attempted methods for the quantitative estimation of bile acids in conditions of hepatic disease are well described, but it is tacitly admitted that none of them has as yet proved satisfactory for routine clinical work. This monograph is indispensable to physiologists and to physicians specially interested in the problems of hepatic and biliary disease.

GLAISTER'S MEDICAL JURISPRUDENCE

The fact that a textbook has reached its fifth edition within a period of thirty years is good evidence that it is appreciated by that section of the public for which it is written. Professor Glaister has been engaged in medico-legal practice for about half a century, and his book bears evidence throughout of the practical first-hand knowledge of legal medicine accumulated during that period. In the latest edition,[2] the authors, father and son, have revised the text to a certain extent, and have included notes on recent legislation of interest to medical readers, but it is difficult to understand the omission of all reference to the Mental Treatment Act, which was before Parliament as a Bill in 1929 and passed into law in 1930. Nor have the authors taken any cognizance of the Road Traffic Act, which introduces a new and far-reaching principle in connexion with charges of intoxication brought against motorists. These statutory changes are of more interest to the practitioner than the new legal matter which has been included. A certain number of illustrations have been deleted, but there are others which could be removed without detracting from the value of the book—for example, Figs. 55 and 60 (stab wounds), Fig. 109 (a section of lung tissue), Fig. 117 (pus from gonorrhoea), and Fig. 167 (adipocere) serve no useful purpose. In the section on identification, a description of finger-prints and their classification occupies more than 14 pages; this is too detailed for the medical practitioner, and is of no value to the finger-print specialist, who must necessarily have much fuller information. The effect of putrefaction on skin papillae, the reconstruction and preservation of finger-tip skin, and the chemical treatment and development of invisible prints, subjects which are of interest to the medical man, are not touched upon. The chapter on hairs has been enriched by the addition of five excellent plates. The section on bloodstains has, to a certain extent, been rewritten, but the precipitin test has not been treated with that clearness which the student expects, and we regret an implication to the effect that the phenolphthalein or so-called Kastle-Meyer test is a definite test for blood.

The section on injuries and death from violence is treated in a masterly manner, and is full of practical detail, and documented with cases from the authors' ample experience. This section could be improved, not by the introduction of more material, but by greater care in its presentation. Many valuable observations are obscured by the method of expression. Take the following sentence, dealing with fractures of the skull:

> "The force being one of compression, acting in direction of the line of impact, compresses the skull and its contents, in lateral directions, thereby producing points of distension, due to resistance, their line being at right angles to the line of force, at which points the fractures take place, and at which the separation of the fractured surface is greatest; and from these, radiating toward the point of impact, and oppositely to the point of distension run the lines of fracture."

This certainly conveys the authors' meaning, but it is too involved to be of real value to the student trying to obtain some general knowledge of the effect of violence applied to the head. The sections on pregnancy, infanticide, abortion, rape, etc., have been left very much as they were, and indeed are so full and informative that little revision is necessary. It is to be noted, however, that the authors still retain the Abderhalden test for pregnancy, but make no mention of the newer Zondek-Aschheim test. The chapter on cases of insensibility is of considerable value, especially to the young practitioner. The chemical side of the toxicological section is weak in general, and unequal. The authors give considerable detail about the isolation and detection of certain poisons and none at all about many others. This section does not convey the impression of careful revision, and we note the absence of reference to tetra-ethyl lead, or to thallium, which has caused a number of cases of poisoning. In the description of carbon monoxide poisoning there is no mention of Hartridge's valuable contribution to the quantitative estimation of the substance, although his reversion spectroscope has been in use by medical jurists for some years; and the qualitative tests are inaccurately described.

This notice of an old-established work must be viewed in the right perspective. Glaister's book is of sufficient merit and is sufficiently well known to withstand criticism; but when a work is so well established, the author should, in producing a new edition, keep the material strictly up to date in his own interest. Moreover, with each new edition an attempt should be made, if the author has time, to improve the style of presentation.

RADIOLOGY OF THE CHEST IN CHILDHOOD

Dr. STOLOFF's book on the radiology of the chest in children[3] approaches this subject from the aspect of the clinician who is also trained in radiology, for "the best radiologist is the man who knows the complete history of the patient, who knows the clinical findings, examines him personally, fluoroscopes him if necessary, and puts

together all these data before he issues his report." This is the ideal method when circumstances permit, but it is always advisable for both clinician and radiologist to discuss their respective findings before making a diagnosis, for it must not be forgotten that the radiologist sees only shadows and not the real pathological process, and that his interpretation can be just as debatable as the clinician's observations. The book deals with the radiology of the various diseases of the trachea, bronchi, lungs, pleurae, mediastinum, diaphragm, and chest wall: the heart is not considered. The findings are discussed more in relation to pathology than to clinical medicine, and little attention is paid to the subject of radiological technique. The author, however, advises the employment of the erect, inspiratory, dorsoventral position for pulmonary work, and includes a number of diagrams illustrating his technique which would be improved by a few words of explanation.

The largest section of the volume considers the radiology of primary tuberculosis. The author bases its diagnosis and differentiation from non-tuberculous lesions on visualization of (1) the primary focus, (2) the regional lymphatic nodes, which are described in detail, and necessarily supported by (3) a positive tuberculin reaction. Equally interesting are his remarks on broncho-pneumonia, for it is common for infants to have no definite physical signs of pulmonary infiltration and yet a radiogram may reveal broncho-pneumonic patches, sometimes surprisingly large. The reverse is also true: that in cases of unquestioned clinical or pathological evidence of a respiratory affection, the *x*-ray examination may have revealed no evidence of infiltration. But a book of this type depends more on its illustrations than on its text, and the author has freely illustrated his points with radiograms of an extraordinarily high standard. A special feature is made of serial radiograms, which are of inestimable value in the study of the pathogenesis and evolution of many pathological processes. They illustrate, for example, the development of a primary tuberculous lesion and its eventual healing by calcification, also the development from its earliest stages of a pneumonic process. Starting as a faint shadow due to engorgement of the vessels and slight exudation, it increases progressively in density, but generally does not affect the entire lobe. The different terminations of the pneumonic process are well illustrated: resolution in one case, the development of an empyema in another, and of a lung abscess in a third. A number of simple line diagrams illustrating and explaining the radiological appearances are included; those advocating the value of the lordotic position in the diagnosis of the pathological conditions affecting the large interlobar fissures are particularly striking.

FUNGOID INFECTIONS OF MAN

It is now eighteen years since the publication of the first edition of Professor R. O. STEIN'S monograph on the fungoid infections of man.[4] During that time our knowledge of the subject has greatly increased, and it has become of much wider interest. Diseases caused by fungi of different kinds are now known to be by no means limited to the surface of the skin and solely to concern the dermatologist, but to penetrate much deeper and to invade the realms of internal medicine. Sporotrichosis and blastomycosis, as well as actinomycosis, are recognized as serious infections. It has also been shown that many of the pus-producing varieties of ringworm evoke systemic reactions which give rise to cutaneous eruptions known as trichophytides and also cause the production of antibodies in the blood serum of those affected. These phenomena, which have been studied principally by Bruno Bloch and his pupils, are all adequately discussed in the present volume, but perhaps the most valuable part of Professor Stein's work consists of the numerous illustrations, which provide excellent representations of all the chief clinical varieties of fungoid infection to which the human integument is liable, and also illustrate adequately the microscopical appearances of the infecting fungi and their cultural characteristics. Besides eighty-one other illustrations there are no fewer than twenty-nine coloured plates, and these, which are obviously based on wax models, are extremely clear and good.

The chief fault we have to find with Dr. Stein's book is that he has omitted all reference to the recent work on the genus *Monilia*, which, during the last four years, has been shown by the researches of MacLeod, Dowling, and Garner to be of unexpected importance in the causation of various dermatoses, of which seborrhoeic eczema is the most frequent. The discovery that the organism formerly known as the spore of Malassez or the "bottle bacillus" is really only one stage of a monilia is certainly the most important advance in cutaneous pathology made in recent years, and in a monograph on mycelial infections it should not be ignored.

ALLERGY REVIEWED

The subject of anaphylaxis, with its important side-issues immunity and allergic disease, is now in a highly interesting and rapidly advancing stage. An enormous literature has accumulated, and, as F. M. RACKEMANN remarks in the first chapter of *Clinical Allergy*,[5] "It is difficult to realize that anaphylaxis was almost unknown up to the year 1900 . . . and the entire development of the conception of human allergy has taken place since 1915." The chief aims of this book are a summing-up of the great mass of evidence and a definition of the present-day conception of the phenomenon, and the author is to be congratulated on the way in which he has undertaken a stupendous task. There is a foreword by Professor Hans Zinsser, who refers to the importance of putting the immunological point of view before the clinician, and the clinical point of view before the immunologist.

Starting with the more theoretical aspects of hypersensitiveness and anaphylaxis, Dr. Rackemann passes on to the clinical manifestations and treatment of serum disease, hay fever, asthma, and other allergic conditions. A very difficult subject is dealt with, on the whole, in a masterly and readable fashion, and it is not the author's fault that until we know more of the ultimate nature of the processes at work, the complicated and somewhat confusing nomenclature of immunology, with its "allergens," "antibodies," "atopic reagins," "haptins," and the like, has to be used for purposes of classification. As Geoffrey Keynes remarks elsewhere, "*Ignorance must be abbreviated.*" In the more clinical aspects the author gives an unbiased account of the present state of knowledge, and any speculations he may occasionally be tempted to make are tempered by sound judgement. Most readers will agree that careful history-taking, and appropriate experiment, are much more important in the investigation of the exciting causes of asthma than indiscriminate skin tests, and a certain number will share the author's scepticism about the value of nose and throat operations. We might have expected a rather more detailed description of Van Leeuwen's methods in the investigation and treatment of

[5] *Clinical Allergy, particularly Asthma and Hay Fever.* By Francis M. Rackemann, M.D. The Macmillan Medical Monographs. New York: The Macmillan Company; London: Macmillan and Co., Ltd. 1931. (Pp. x + 617; 29 figures. £2 4s. net.)

asthma, but his opinions are carefully weighed, and Dr. Rackemann's wide experience gives much value to his statements on the results of therapeutic measures.

The work does not pretend to tell much that is new, yet there must be few readers whose mastery of the subject is so complete that they will not find many gaps in their knowledge. A useful bibliography is appended to each chapter. There is no doubt that *Clinical Allergy* will make a wide appeal both to clinicians and to laboratory workers. We suggest, therefore, that certain data—for example, the distribution of pollens—should in future editions be extended to countries other than the United States, and that such phrases as "the size of a fifty-cent piece," which convey little to the average English reader, should not be used.

THE CHARAKA CLUB

The Charaka Club, recalling by its name the authority on Brahminical medicine during the second century of the Christian era, consists of about thirty American medical men, and is well known among those fond of literary productions for its attractive *Proceedings*,[6] published from time to time. The seventh volume, of which 575 copies are printed, worthily maintains the club's reputation for conveying out-of-the-way information with a light touch. Most of the twenty-four papers read to the club and now reproduced are not strictly medical in tone; there are several humorous fragments in verse by Dr. G. D. Stewart, one, however, being "A Tired Doctor's Prayer"; "Sketching Boats on the China Coast," by Dr. R. L. Dickinson, carries the reader far away from his professional atmosphere; and Dr. E. L. Keyes's gloss on Paul Géraldy's "Notes on Love," which is entitled "The Stuff that Dreams are made of," has a psychological bearing, as well as a most pleasing style. There are two affectionate tributes to senior members of the club—G. L. Walton and "C. L. D. "(ana), and a sympathetic notice of W. B. James (1858–1927), who was determined "to make life pleasanter for his patients and friends, saner for his contemporaries and successors." Success crowned his efforts. Dr. Camac talks on the papyrus industry of the ancients, and this, like the article on Robert Estienne, the scholar-printer, may perhaps be regarded as a transition to those on medical history, such as Dr. E. C. Streeter's essay on the education of the barber-surgeons in France, and the hierarchy of the Monros, which Dr. B. Sachs begins with the graphic sentence, "Alexander Primus, Secundus, et Tertius may be said not only of the Romanoffs, but of the Monros as well, who were the czars of medicine and surgery in Edinburgh over a period of one hundred and twenty-five years." The most serious and considerable article is that on "The Journal of Jean Héroard, Physician to Louis XIII," contributed by Dr. Francis R. Packard, editor of the *Annals of Medical History*. These papers diffuse a pleasant impression of the clubbable relaxations of busy members of our profession.

NOTES ON BOOKS

The March number of the *Annals of Medical History*[7] contains seven articles on various subjects as far apart as Galen and the "Totentanz, 1914–18," which comes into the concluding instalment of Professor A. Scott Warthin's extremely interesting and generously illustrated account of "The Physician of the Dance of Death." Dr. C. W. Burr's paper read at the Galen memorial meeting at Philadelphia last October appropriately accompanies Dr. Joseph Walsh's refutation of the charges of cowardice made against Galen for leaving his native city Pergamum when a rebellion with its associated dangers broke out, and for absenting himself from Rome at the time the plague occurred there. Sir D'Arcy Power, in his address before the Section on Medical History of the College of Physicians of Philadelphia on December 8th last, dealing with "Touchpieces and the Cure of the King's Evil," tells us that, though the Hanoverian kings never touched, it was not until some years after the accession of George I that the form of prayer special to the occasion was removed from the Prayer Book, its last appearance being in Basket's folio edition, published by the University of Oxford in 1715. In a scholarly article on the history of lead poisoning Professor R. H. Major of Kansas City finds the first recognition of this disease in the poems of Nikander, whom he calls "the poet laureate of lead colic," in the second century B.C. Dr. D. I. Macht of Baltimore contributes an appreciation of Professor Louis Lewin (1850–1929), the pharmacologist, toxicologist, and medical historian, and supplies a list of his 227 publications. The review by Dr. T. H. Bast of the life and works of Max J. S. Schultze gives the history of his new cell theory and of the establishment of his *Archiv für Mikroskopische Anatomie* in 1865. A descriptive list of the incunabula in the library of the College of Physicians of Philadelphia shows that there are no fewer than 401. An illustrated editorial reports on the eighth Congress of the International Society of the History of Medicine, and there are good reviews by the editor and Professor Thomas McCrae of recent books.

We have received from Messrs. E. and S. Livingstone, of Teviot Place, Edinburgh, the following additions to their Catechism Series.[8] *Medicine*, Part II; *Chemistry*, Part II; *Pathology*, Part V. These continue the system of instruction begun in previous parts. The same publishers have also issued a copy of the *Fellowship Examination Papers*[9] for the higher diploma of the Royal College of Surgeons of Edinburgh, from 1927 to 1930.

Volume iii of the late Sir FREDERICK SMITH'S *Early History of Veterinary Literature*[10] deals with the period 1800–23. It is an important era in the development of veterinary science in England. The London school had been in existence for eight years, but it had had an unfortunate start, as it lost its principal two years after his appointment, and, immediately afterwards, its most powerful supporter, John Hunter. It was unfortunate, too, that the next principal was not a veterinarian, and that its examiners were physicians and surgeons. Teaching was limited to the horse, and the other animals were almost entirely neglected. Quacks flourished throughout the country. Free trade introduced the great epizootic diseases from abroad, and there was no one who understood them. A knowledge of the work of this period is essential for an understanding of the tremendous difficulties which veterinary science had later to overcome in the nineteenth century. Medical history is under a deep obligation to General Smith for bringing these facts together. Before his death he had collected material relating to the period up to 1869, and it is hoped that this will soon be published to complete what is a most valuable piece of work.

Parts VII and VIII in the *Synthetic Anatomy*[11] series, which is being published by Messrs Baillière, Tindall and Cox, are designed for use together, several plates in each part interlocking in such a way as to facilitate the complete trunk in various planes being indicated diagrammatically. This series of anatomical drawings on

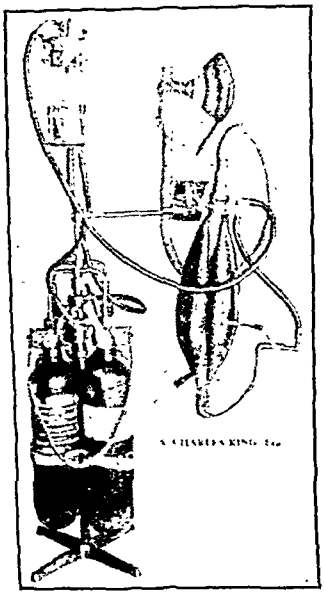
transparent sheets has been designed by Dr. J. E. CHEESMAN, and is now nearly complete, the only parts remaining to be published being those on "The brain" and "The male and the female perineum." Each part is purchasable separately, price 3s. 2d. post free; loose-leaf binding cases to hold the twelve parts may be obtained, price 3s. 3d. post free.

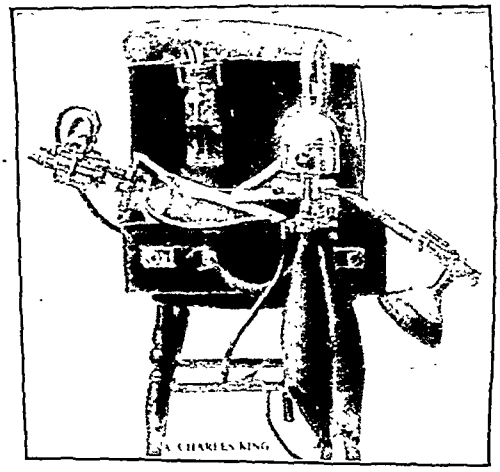
PREPARATIONS AND APPLIANCES

A SIMPLE GAS AND OXYGEN APPARATUS

Dr. E. ROLAND WILLIAMS (Maenclochog) writes: The portable apparatus illustrated has been used by me for a year. It allows an ordinary "dental gas" apparatus to be used for



administering gas and oxygen with an intermittent flow varying in accordance with the patient's breathing. Inclusive of one 100-gallon cylinder of gas and one 30-gallon cylinder of oxygen, it all packs into the attaché-case shown, the total



weight being 31 lb. Reducing valves are fitted to the cylinders. Those illustrated are Dr. MacGill's modification of the Adams valve. The "Endurance" regulators manufactured by the British Oxygen Co. for acetylene welding also make suitable reducing valves. The gas bag is fitted with a light steel spring framework, the springs not being powerful enough to impede rebreathing. At the side of the bag is suspended an ordinary gas tap. By means of a light rod the lever of this tap is connected to one of the springs of the framework in such a way that when the bag is moderately distended the tap is turned off. A flow-meter of the Boyle type provides a sight feed. Two ordinary Higginson syringe valves (Rigby ball valves would also be suitable) prevent the water from being forced out under the gas pressure. When not in use with a stand, this flow-meter hooks over a bed rail or over the lid of the bag. (The use of the "bubble bottle" is not essential; the proportion of gases can also be regulated by the graduated scales shown behind the tap levers on the reducing valves. A further refinement of control is obtainable by fitting a two-way tap controlling the bag inlet.) The gas bag is attached to a strong universal clip of the "ajustolite" pattern. This can be clipped on to the side of the attaché-case, or on to the bed rail. For nasal administration in dental cases it is conveniently clipped to the back of a chair. Fitting into the bag mount is a wide-bore flexible breathing tube, as used in the Walton apparatus. At the end of this is an ordinary Barth valve-piece. The face-piece used is a metal one, with three small hooks soldered on to enable it to be kept in position by an elastic T-piece.

For obstetric use the following device is employed: An adjustable stop is set so that the valves cannot be pulled further over than half-way between "valves" and "no valves." This gives the desirable amount of rebreathing, and economizes gas. A spiral spring is clipped on to connect the valve-piece to the end of the breathing tube, as shown. At the beginning of a pain the patient applies the face-piece (if it is not already strapped on) and pulls the valve-piece over, against the spring, as far as it will go (that is, to the "half rebreathing" position). Mixture then begins to flow automatically as she breathes. When she becomes anaesthetized and lets go, the spring returns the valve to the "air" position, at the same time stopping the flow of the gases. To secure a continuous supply the spring can instantly be unhooked.

The apparatus described has been used by me mainly under domestic conditions, and the presence of open fires and naked lights has generally prevented ether from being used with the gases. For the addition of ether vapour I suggest the arrangement illustrated, which has seemed to work satisfactorily on the very few occasions when it was needed and could be used. A Clover inhaler is interposed between the bag mount and the breathing tube by means of a simple adaptor, which keeps the Clover in the "no-ether" position when gas and oxygen mixture alone is in use. By revolving the inhaler body, however, any desired concentration of ether vapour can be added. In this way the ether is instantly available as an independent anaesthetic by the Clover method, if the gases, for any reason, cease to flow. In the side of the adaptor there is also a wide air-port normally stoppered by a rubber bung. Withdrawal of this bung (in the event, say, of a leaky or burst bag requiring to be repaired or changed) gives "open ether" through the Clover. In this case it is desirable to wrap a towel, wrung out of hot water, round a section of the breathing tube to warm the ether vapour.

The stand model illustrated was made by Messrs. A. C. King, Ltd., of Devonshire Street, W.

A LITHOTOMY SUPPORT

Dr. EDWARD BARON (London, N.15) writes: I have devised a lithotomy support which remedies the defects of Clover's crutch, and which is light, collapsible, and easily carried in the midwifery bag. It consists of adjustable bands of webbing arranged to fit on to the shoulders instead of the neck, pads to fit below the knees to which the four ends of the bands are secured, and a metal support, which, when fixed in position, not only keeps the legs apart, but also outwardly directed from the knees, it being then impossible for the patient to cause a collapse of the support. It should be applied either before or during anaesthesia, preferably with the patient in the dorsal position. The bands are placed across the shoulders, with the transverse connecting piece behind. The pads, with the incorporated metal plates placed along the inner surface of each tibia, are then fixed below the knees by buckles. The bands from the back of the shoulders are clipped on to the outer side of the knee pads, and the front bands are attached to the inner side of the pads. Adjusting bars enable the bands to be lengthened or shortened until complete flexion of each leg is obtained. The collapsible metal support consists of four links, the inner two forming the cross-bar when opened out. To each outer end a link is pivoted at an obtuse angle, and these latter links fit into slots in the knee pads. When these are inserted, and the inner links opened out until automatically locked, there is then formed a leg separator and abductor. The advantages are: complete flexion at hip and knee, with separation and abduction of legs, support from the shoulders, exclusion of the legs from the doctor's hands or instruments, excellent view of the area required, and compactness.

The support has been made for me by Messrs C. J. Hewlett and Son, Ltd., 35–42, Charlotte Street, E.C.2.

SPECIALIZATION IN THE MEDICAL CURRICULUM

In his recent Silvanus Thompson Memorial Lecture Dr. A. E. Barclay discusses such a well-worn topic as the dangers of specialization in medicine, and he finds the beginnings of these mischiefs in the lack of co-ordination of the various teaching schemes that constitute the medical curriculum. Each teacher, the argument runs, inevitably cultivates on the highest scale his own particular department and claims for it a place in the sun, with little or no regard to its actual values in medical practice, and with scanty consideration either for the schemes of his colleagues or for the brevity of human life. Thus from the outset the student is led to believe that to become a "specialist" is the true ideal, although at the same time the instruction given in each subject is quite inadequate for this purpose, and remains for the majority of students mere "detail to cram up for examination." Under such influences the curriculum is unduly and unnecessarily prolonged; the student is burdened with facts which make no contribution to his work as a practitioner; and, newly qualified, he escapes into duties and responsibilities for which he is very imperfectly equipped. The remedies which Dr. Barclay proposes for this unhappy state of affairs are the creation of a dictator who shall determine what each teacher shall or shall not include in "the routine outline course"; the subordination of each departmental interest to a precise and practical educational purpose; the bringing of all branches of the biological services into mechanical and organic relations with the hospital wards; and the introduction of general practitioners as members of the teaching staffs.

That the medical curriculum is in many respects unsatisfactory is a proposition which few will be prepared to deny, and the suggestion may even be ventured that so long as medicine and the sciences on which it depends are alive and in movement, the perfect curriculum will not be achieved. The edifice carefully constructed to-day will meet with new assaults on the morrow, and will certainly be found wanting as tested by new conditions and new developments. It is in vain to sigh for the imposition of a fixed, rigid, and perfect educational pattern, and although dictators, it is true, are just now fashionable in many quarters, we doubt whether Dr. Barclay's summons will produce either the commanding autocrat or the submissive constituency; and even if the judge and ruler arrived we feel sure that his days would not be long in the land. It is not by the aid of such an ally that Dr. Barclay may hope to reconstruct the medical curriculum. The claim for the establishment of closer relations between the several parts of the curriculum has a much more reasonable quality. Admittedly each teacher is apt to exaggerate the relative importance of his own subject and to push details into undue prominence, though we can hardly believe that individualism in our medical schools and faculties is quite so rampant as Dr. Barclay's indictment suggests. The recent attempt in some of the schools to bring the teacher of physiology into relation with clinical medicine shows that not only without, but also within the citadel, there are advocates of effective co-ordination. The critics therefore may take heart of grace.

The complaint that the student is taught much that is of no practical value to him except as an aid to success in examinations, and that in the end he is "let loose" on the public while still inefficient, can no doubt be presented in a plausible setting. Yet, read by the inexperienced, it is in large measure misleading. Medical education means, and ought to mean, something more than a mere technical training, and to treat the scientific subjects in the curriculum as mere handmaids to practical medicine and practical surgery would not form for the best minds an attractive discipline. What medicine must offer if it is to remain a liberal education and a liberal profession is an opportunity for mental culture and for individual development, and this fundamental influence, not less than due regard to the art and craft of the calling, is essential to the attainment of the highest levels as tested by the sure verdict of time. It is in an atmosphere, not of rigid rules, but of mental methods, that the practitioner will find the training that promises the fullest opportunity for self-realization and for enlarging service. As for efficiency, the term is a relative one. Who will boast himself in general medical work to be efficient, not merely at the end of the curriculum, but even at the end of life? It is much if in his undergraduate days the student has acquired a right attitude towards his professional duties and responsibilities, has learned the virtues of accuracy and thoroughness in observation, and has enjoyed a sufficient body of experience to enable him to utilize whatever opportunities fate may bring to him. So equipped, he will always be moving towards efficiency, and sooner or later will in large measure attain it. Certainly if he is to be held in chains until he can leap fully armed into the arena, not five or even ten years will see him on his feet. What is possible in the course of the curriculum is the establishment of a habit of mind and the recognition of sound principles illustrated by such clinical experiences as may be carefully studied in a limited space of time. Upon such a foundation, followed by the cultivation of opportunities for mental discipline and for practical training, the right type of student will make himself a good doctor and an educated man; and he does this to-day even though the medical curriculum leaves many loopholes for the critics. These may well continue their useful service, for while perfection will escape them

they may always hope to press for adjustments to meet the changing demands of the day and hour.

Dr. Barclay recalls in particular the advantages of the discarded apprenticeship system, and thinks that these might be regained were general practitioners included in the teaching staffs of the medical schools. The really effective and inspiring teacher is not a frequent figure at any time, and when he can be found a medical school ought to be glad to secure him, whatever his professional activities. But general practice in action must be learned in general practice, and here more than anywhere else talk about the art apart from the routine of daily service is little to the purpose. In any event, short cuts in the matter of medical education are no substitute for the sure though slow methods of scientific and clinical discipline. Here, and here alone, is the sound foundation on which the fullest measure of efficiency may gradually be developed.

CENTRES FOR RHEUMATISM

It is now little more than a year since the British Red Cross Society's centre in London for the treatment and investigation of rheumatism was opened by the Queen for the reception of patients.[1] In this brief period the work of the clinic has increased to such an extent, and the sphere of its utility has become so obvious, that there is now apparently a movement on foot in many of the large industrial areas of England and Wales to establish local centres similar in plan to that in Regent's Park, where serious work on and for rheumatism may be carried out. The authorities in many of these areas have, not unnaturally, applied to the Red Cross Society for guidance in their project, and for details of the experience, both medical and financial, which has been gained during the year at Peto Place. The British Red Cross Society has now issued a comprehensive pamphlet prepared in response to these demands. Its clinic is the outcome of a national appeal launched in 1929 at the urgent representation of several Labour and health organizations, with the blessing of the medical profession, and the sympathetic approval of the Ministry of Health. It is the only institution of its type in England at present, and is reputed to be the finest in Europe. Though the experimental stages are admittedly not yet at an end, it is submitted that there is ample evidence to show that the venture has been amply justified, and that there can now be no legitimate doubt regarding the need for such clinics or the general plan which should be followed.

The recommendations made are based on the provision of clinics which shall (as at Peto Place) treat a maximum of 500 patients daily (400 in the general block and 100 in the private block) and where treatment shall be given from 8.30 a.m. until 9.30 p.m. every day except Sunday. The appointment system is favoured, with an average of two or three consultation periods a day. The medical administration should be under the control of six physicians with a competent knowledge of general medicine, in addition to a particular interest in rheumatism, since control by a single medical director in an institution of this kind is, in the opinion of the society, contrary to the best traditions of English medicine. The control of non-medical matters and finance should be in the hands of a house committee meeting monthly to receive reports from the medical board, matron, secretary, and almoner. This committee should decide all matters relating to the building, and should appoint all staff, though medical appointments should only be made on the recommendation of the medical board. With regard to the specialist medical staff, this was felt at first to be perhaps a luxury, and it was not appointed for some months after the opening of the clinic. It is interesting, therefore, to find that the minimum personnel now recommended in this pamphlet is as follows: a pathologist who is equipped for both bacteriological and biochemical work, or who has hospital facilities for dealing with both classes of work (this appointment should preferably be held by a man engaged in research in addition to his routine work); a radiologist, who need not be a whole-time officer; a dental surgeon; an oto-laryngologist, who should attend for one session each week; an orthopaedic surgeon; a gynaecologist; a general surgeon; and an anaesthetist. It is advocated, further, that one of the general physicians should have a specialized knowledge of hydrology and another of electrotherapeutics, whilst a whole-time "medical registrar" to supervise the carrying out of the treatment is essential. The details of running such a clinic are exhaustively discussed under the headings of "The building," "General administration," "Medical administration," "The matron's department," "The almoner's department," "Schedule of rooms, etc.," "Equipment, furniture, and linen," and "Summary of staff." Much well-informed labour must have been expended in compiling this valuable document, which is a mine of information, and should be of great use, also, to those responsible for medical institutions of all sorts.

The British Red Cross Society makes it plain that while realizing, and indeed emphasizing, the need for rheumatism centres outside London, it feels that there would be a real danger, in view of the rapidly increasing scientific interest which is being taken in "physical medicine," if such clinics were to be established by all and sundry with no links, however loose, through which the campaign against rheumatism could be co-ordinated and pushed forward as a concerted effort on the part of everybody concerned in the movement. By these means, and by these means alone, the Red Cross Society feels that the grave social and industrial burden of chronic rheumatism may in time be lifted, even as the burden of tuberculosis was lightened by similar organization three decades ago. The basis of the Red Cross scheme is a simple and elastic linking up of organizations, and the raising of

[1] *British Medical Journal*, 1930, i, 409.

a national fund to assist in providing, in one place, the desired equipment, in another the desired accommodation, in a third no more, perhaps, than the interchange of information. It advocates, moreover, the association, wherever possible, of the clinics for rheumatism with voluntary or municipal hospitals, of which they might with advantage form a department. In this case auxiliary clinics could be established in surrounding small towns and villages to work in conjunction with them. It is gratifying to find that such an urgent problem of modern life is being seriously tackled by a body with the influence and importance of the British Red Cross Society.

THE DISCOVERY OF THE SPIROCHAETE

The discovery of the virus of syphilis forms an interesting chapter in medical history, and is well described in Dr. Erich Hoffmann's Lectures on the Twenty-fifth Anniversary of the Discovery of the Spirochaete.[1] Discoverers of new facts, if the latter are of any considerable significance, may be said to fall into two classes—the premature and the opportune. The former, advancing their discoveries before the times are ripe for them, usually meet with scorn, if not with obloquy, while the latter immediately receive a recognition somewhat analogous to that of admission to the calendar of the saints. The account of an effective discovery should therefore include some intimation of the prevailing scientific sentiment which renders the discovery acceptable. With regard to the spirochaete of syphilis, Dr. Hoffmann has gone very fully into this aspect of the subject. Interest in the causation of syphilis had recently been revived by the discovery of Metchnikoff and Roux that the disease was transmissible to the apes. Klingmüller also had shown that the virus failed to pass through a Berkefeld filter, and it was concluded from this—together with the fact (erroneous, as it turned out) that the disease could not be acquired from the cadaver—that probably the virus was a relatively large organism, such as a protozoon, rather than a bacterium. Among such organisms known at the time were the trypanosome and Obermeier's spirochaete; and Roux had described several varieties of the latter type in diseases of the mouth and genitalia. About this time Siegel, using Schaudinn's method, advanced the view that small-pox, measles, scarlet fever, and syphilis were caused by protozoa belonging to the family of the flagellata, and he claimed to have found the organism in the blood of syphilitic patients. This alleged discovery had the support of Professor Schulze and other prominent members of the Berlin Academy of Science; and the German Government also was impressed with its importance. Accordingly, the Minister of Public Health was instructed to nominate a small committee of investigation. Schaudinn, already known as a protozoologist of outstanding ability, was appointed as bacteriologist, Hoffmann as histologist, and Neumann (who later retired from the committee) as experimentalist. Hoffmann prepared smears and slides which he considered likely to contain the virus and to be as free as possible from contamination; these were examined by Schaudinn, and at the first sitting in March, 1905, a fine and a coarse spirochaete were demonstrated in specimens from a papule and condyloma. Deeper structures were then studied, and the examination of preparations from enlarged glands proved that the finer variety was present alone. Subsequent investigation was directed to ascertaining how far the new organism conformed to Koch's postulates. Professor Hoffmann exhibits a very natural enthusiasm in recounting the circumstances of the discovery, in which he played an essential part.

[1] *Vorträge und Urkunden zur 25 jährigen Wiederkehr der Entdeckung des Syphiliserregers (Spirochaeta pallida).* Von Dr. Erich Hoffmann. Berlin: S. Karger. (M.7.)

REFRESHER COURSES FOR SHIP SURGEONS

Travellers by sea are becoming more and more exacting in their demands upon the ship surgeon. The old days of temporization are past; it is no longer enough to treat gastronomic catastrophes with a wave of the hand, or to be content with first-aid methods in accidents on board ship. The medical officer of a passenger vessel must be surgeon, psychologist, sanitarian, and sailor rolled into one. Early in 1930 the British Medical Association, responsive to suggestions from the Ministry of Health, and alive to the need of some form of refresher course for the ship surgeon, appointed a special committee, consisting of members qualified to indicate the general framework of a post-graduate educational scheme. This body met several times during 1930, ultimately drafting a skeleton policy for the approval of the Council, which, at its November meeting, agreed that success could only result by co-operation with the shipping companies concerned; a conference was therefore convened by the Council for March, 1931. Every interested party was represented; delegates attended from the teaching bodies, the shipping companies, the Ministry of Health, the Board of Trade, the Port of London Sanitary Authority, and the British Medical Association itself. It was pointed out that the Association was acting only in an advisory capacity in the hope of establishing liaison between the companies and the teaching bodies. The business of the conference was to select the most useful subjects of study, to determine the most suitable periods of the year for holding the course, and to arrange the classes. A resolution was passed by the conference, "that no examination should be held at the end of the proposed courses of instruction, and that, if any certificates were issued, they should represent merely a record of attendance." The Seamen's Hospital Society indicated that it was prepared to proceed with the establishment of classes forthwith; similar assurances were given by the London School of Hygiene and Tropical Medicine, and by the University of Liverpool. Some courses have already been arranged; these were advertised in the *Journal* of April 11th, and will be inaugurated this summer. It is understood that the present syllabus is merely an experimental one; the conference decided that the question of holding future courses should be determined by the results of the existing programme. Much depends upon the response made by the doctors concerned. The Association has fulfilled its function in launching a new training ship in which the ship surgeon will have ample opportunity for perfecting himself in modern methods of practice. When, returned to his ordinary duties, he may be confronted with one or more of the abstruse problems of therapeutics, he will, so to speak, be less at sea than before.

STREPTOCOCCAL INFECTIONS

The first quarterly number of the *Guy's Hospital Reports*[1] for this year is, with the exception of Mr. R. C. Brock's short but concise paper on the platelet count in tuberculosis, devoted to a very valuable symposium on streptococcal infections, which thus forms a companion to that on staphylococcal infections in the April instalment of last year. In the opening article Drs. J. A. Ryle and R. E. Smith describe the natural history, prognosis, and treatment of streptococcal fever, which includes both streptococcal bacteriaemia and septicaemia, but excludes scarlet fever, erysipelas, and infective endocarditis. Attention is called to four clinical manifestations of streptococcal fever due to a haemolytic strain—namely, diarrhoea, albuminuria with red blood cells and casts, rapidly progressive anaemia, and a smooth, red, desquamated, and sore tongue. An important conclusion about treatment is that mercurochrome and other chemical antiseptics should be avoided, and that the use of antistreptococcal serum is open to grave doubt. In his account of streptococcal puerperal sepsis Mr. Gibberd takes the same view as regards these therapeutic measures. Mr. Mollison, however, urges the use of antistreptococcal serum in acute streptococcal throat infections unless there is some definite contra-indication, such as a known sensitivity to serum. In a general survey of the significance of the streptococci in clinical medicine Dr. F. A. Knott points out that a streptococcal infection produces first a toxaemia, then extensive toxic effects in the tissues, and, lastly, a general septicaemia, and that to exert any well-marked influence antiserum must be employed in the first stage, and not delayed until a positive blood culture is obtained. Mr. T. B. Layton writes at considerable length on haemolytic streptococci in the mastoid, and shows that routine cultivation from the bone is important in order to advance knowledge of the sequence of events in this condition. In his clear account of cutaneous diseases Dr. H. W. Barber recognizes two groups of streptococcal dermatoses: first, those due to invasion of the skin by living and actively multiplying micro-organisms, or external infective dermatoses ; and, secondly, toxic eruptions of varying morphological and histological types, probably allergic in nature, which, being comparable to the tuberculides, may conveniently be called streptococcides.

DIFFICULTIES OF MEDICAL PRACTICE IN CHINA

The right of foreigners resident in China to be tried by their own nationals is the principal subject of controversy that remains among the few outstanding diplomatic differences between China and the Foreign Powers, and is summed up under the term "extra-territoriality." Germany, Russia, and Belgium have already surrendered their former Treaty rights, but the other Powers, while agreeing in principle to such surrender, are holding out till the time when there is more evidence of law and order in China. The medical aspect of this political question, judged by some recent events, is important, and requires watching. In one case, of which information has reached us, a Chinese patient was brought to hospital in the last stages of auto-intoxication, and with a large perineal abscess. Though the chance was slender, the surgeon, a British subject holding the F.R.C.S.Ed. diploma, agreed to open the abscess. The patient died later on, and his death was followed by the visit of six policemen, who entered the surgeon's house while he was dining and marched him off with a pistol held behind his head. With difficulty he was later released by the intervention of the British consul. In Tientsin a German doctor performed an operation on a man's neck. The patient died. The doctor was tried and condemned to a fine of 3,000 dollars and three years' imprisonment. The German Minister protested, and the fine was reduced to 1,500 dollars, and the imprisonment to eighteen months. The German Minister protested again, this time without avail. Among the Chinese themselves medical practice on modern lines is still somewhat risky. The medical superintendent of the Kuling Mission Hospital, a Dr. C. S. Teng (Peking Union Medical College) was called to a case of diphtheria. The patient was the wife of a general, holding high office in one of the armies. Dr. Teng, after diagnosis, sent for a dose of antitoxin, which he at once injected. Death, however, ensued, and the doctor became the subject of a prosecution by the general, who charged him with murder, and claimed 85,000 dollars ; he also petitioned that the court should punish this "evil" doctor and confiscate his property, handing it over to the Government for the establishment of "a good and proper Chinese-style hospital." Eventually the local court found Dr. Teng, who had been arrested and imprisoned, to have been guilty of a mistake in judgement, and imposed on him a fine of 800 dollars. Leave to appeal was refused, and an attempt on the doctor's part to prosecute the general for unlawful imprisonment and defamation of character could not be entertained in a civil court, as, by Chinese law, military officials can be tried only in a military court. A meeting of all the foreign doctors at Kinkiang examined the case and found that Dr. Teng had not been guilty of any carelessness or malpraxis, but as a result the Kuling Mission Hospital and tuberculosis sanatorium has had to be closed, after many years' useful work. These facts are but incidents in the introduction of Western medicine and surgery to China, where the past decade has seen great advances, though evidently not without dangers from a people many of whom are still prejudiced in favour of the old empiric and other native methods of treatment.

VETERINARY OPERATIONS

Veterinary surgery, in the strict sense of the word, has in the past had severe limitations placed on its scope by economic considerations. It is theoretically possible to perform many operations on the horse or the cow, for example, which would not be justified by the commercial value of the animal. A broken leg in a horse can be healed in the same manner as in man ; but a horse's value depends on its legs, and an animal with a "limp" is useless except, perhaps, for breeding purposes. Similarly the cost of a long convalescence in the case of an ox may far exceed the ultimate value of the animal. In the case of dogs, cats, and pet animals, however, commercial considerations are of less account, and much can be done with these animals which cannot

be attempted with the farm mammals. There is still, of course, the disadvantage that, whereas a human patient can be placed in some form of intelligent constraint in hygienic surroundings for post-operative treatment, dogs and cats try to undo all the work of the surgeon, and cannot be kept under nearly such clean conditions. Nevertheless, much has been done with animals in recent years, and the March number of the *Veterinary Journal* is entirely devoted to articles on surgical operations in dogs and other animals. It is of considerable interest in illustrating the type of work which is now being attempted with animals, describing as it does superficial as well as deep operations, radiology in animal practice, and so on. It serves to emphasize, also, the close connexion between the two branches of surgery, and shows that the differences are due, not to the underlying principles, but to economic and hygienic conditions.

A MEDICAL FILM LIBRARY

Kodak Limited have issued a supplementary catalogue of their medical film library, giving particulars of more than thirty new films now available. These are additional to the sixty which appeared in the original catalogue reviewed in our issue of April 26th, 1930 (p. 791). The new films are grouped under the headings of anatomy, case records, dentistry, orthopaedics, physiology, ray therapy, research, and surgery. Some have been exhibited already at meetings of the Royal Society of Medicine, and of other professional bodies, and we have drawn attention to them in reports —for example, films illustrating the technique of posterior radium barrage in carcinoma of the rectum, employed by Sir Charles Gordon-Watson at St. Bartholomew's Hospital, and cholecystectomy as practised by Mr. Mortimer Woolf. There are a dozen short reels, shown recently in London by Dr. Lorenz Böhler of Vienna, illustrating the treatment of fractures and dislocations of the extremities. One illustrating the reduction and treatment of Colles's fracture occupies about two minutes, and a similar one on fracture of the forearm takes no more than four minutes. Interesting subjects include the operation for acute appendicitis as done in an American theatre; the highly specialized operation of hinged graft for depressed nasal bridge, by Sir Harold Gillies; the operative technique in exophthalmic goitre, by Mr. Cecil Wakeley; and phrenic evulsion and thoracoplasty, by Mr. H. Morriston Davies. From Continental laboratories there are two physiological films dealing with the exposed heart, and with mitral valve insufficiency. Two "research" reels demonstrate the behaviour of spirochaetes. The films are let out on hire by the day, and, with few exceptions, it is stipulated that they must be shown to none save qualified medical practitioners or registered medical students. In some cases the photography is supplemented by animated diagrams, which add greatly to the educative value of the record; the "close-ups" and captions are so arranged that the maximum information is conveyed in the clearest manner. While we hold that the living teacher is better in person than on the screen, there can be no doubt that this series is of great value to the student. The catalogues may be obtained from the Medical Department, Kodak Limited, Kingsway, London, W.C.2.

INCORPORATION OF VITAMINS IN BREAD

In a paper in the February issue of the *Canadian Medical Association Journal*, Drs. Frederick Tisdall, T. H. G. Drake, and Alan Brown of Toronto describe a method for adding vitamin D (in the form of irradiated ergosterol) and vitamins B and E (as wheat germ) to bread. They consider, presumably, that the addition of these substances to the food supply of the general population is desirable, particularly (as they point out) in northern climates, where irradiation of the skin is likely to be deficient. A good supply of vitamin D is essential to growing babies; there is no reason, however, to believe that the amount of vitamin D contained in the ordinary ration of the average adult is not amply sufficient for his needs. Bread plays a prominent part in the food supply of adults, but a small one in that of babies; and the authors seem unduly pessimistic about the vitamin D content of the ordinary baby food—milk. It is possible that good results on the general health of the population might follow an increased consumption of vitamin B, though the point is still open to much controversy. Since vitamin E seems undoubtedly (at least in animal experiments) to increase reproduction, some people might regard the automatic inclusion of this in their diet as an unwarrantable liberty. It seems, on the whole, unlikely that the artificial addition of vitamins to bread would profit any but the firms who could advertise the article to the disadvantage of their rivals.

CONGRESS OF TROPICAL MEDICINE AND HYGIENE

During the International Colonial Exhibition in Paris this coming summer there will be held a congress of tropical medicine and hygiene from July 22nd to 31st, under the presidency of Professor Tanon, who occupies the chair of hygiene in the Paris Faculty of Medicine. The subjects to be discussed include infant and child welfare; the anopheles and stegomyia problems; questions of food, drinking water, and intestinal parasitic diseases in tropical countries; emigration and the exclusion of epidemic diseases at ports; leprosy, and the campaign against syphilis; and trypanosomiasis. Two days will be devoted to aviation in its public health aspects; Dr. Charles Richet will preside over this Section, and there will be a special demonstration of various kinds of equipment. Attention will also be devoted to the French colonial health resorts. Free discussion will be promoted at all the meetings, and a full report will be published. A British exhibit is being prepared by Dr. S. H. Daukes, and this will be situated in the "Cité des Informations" part of the exhibition, where Great Britain has nine stands. Delegates have been invited from the British Government and the leading tropical medicine societies throughout the world. The British representative and liaison officer is Dr. Leonard Robinson. There will be a large number of official receptions and excursions to places of interest. The fee for membership of the congress is 100 francs; friends and relations of those attending will be admitted on payment of 50 francs, and special reductions of travelling expenses are obtainable. A full programme will be published later, and further information may be had from Dr. Robinson, 28, rue de Ponthieu (Champs Elysées), Paris, VIIIe.

EDUCATION IN OBSTETRICS AND GYNAECOLOGY

SYSTEM OF TEACHING IN THE ROYAL FREE HOSPITAL UNIT

BY

DAME LOUISE McILROY, D.B.E., M.D., D.Sc.

PROFESSOR, OBSTETRICAL AND GYNAECOLOGICAL UNIT, LONDON SCHOOL OF MEDICINE FOR WOMEN, UNIVERSITY OF LONDON

Much discussion is taking place as to the possibilities of carrying out the system of teaching which has been recommended by the Government Departmental Committee on Maternal Mortality. The chief difficulties encountered by those who are anxious to improve the training of medical students in obstetrics are the provision of maternity beds and accommodation for resident students. A system of training which has been in practice for a number of years in the Royal Free Hospital may show other schools that there is a possibility of carrying out the recommendations of the committee to some extent.

The Unit was established in February, 1921. It is affiliated to the University of London, and receives an annual grant from the Treasury through the University Grants Committee. The director's salary is paid by this grant, and also subsidiary salaries and expenses. It was the first university obstetrical unit to be established, and it is staffed by women with women students in attendance. Men may attend the post-graduate classes held by the director twice a year.

The hospital provides the Unit with 68 beds. The obstetrical beds number 45—31 for puerperal and ante-natal patients, 6 for V.D. maternity patients, 4 for isolated suspect and septic cases, and 4 for patients during labour. There are 23 gynaecological beds, which are accommodated in the main surgical block. Plans have been completed for the erection of a new building for the Unit, as the present accommodation is inadequate and out of date, but funds are required for its erection. The work of the district in the neighbourhood of the hospital was found to be somewhat restricted, owing to other maternity institutions. In 1926 a maternity clinic was established in Islington to provide attendance on patients in their own homes. The work of this clinic has steadily increased, and has proved itself of great value for teaching purposes. The expenses of the clinic are defrayed by the Scottish Women's Hospitals Memorial Committee of the Royal Free Hospital, which also supplies a motor car for the use of the resident obstetric officer. The rent of the clinic is defrayed by Lord Riddell, the president of the hospital. Grants from the Ministry of Health (now L.C.C. administration) also enable the clinic to be run without any financial aid from the hospital.

STAFF OF THE UNIT

The staff consists of a whole-time director, a senior part-time assistant, a whole-time second assistant, and a whole-time resident third assistant, who acts as tutor and is responsible for the students in residence. A part-time registrar is provided, and there are two house-surgeons. A senior obstetric officer is in residence at the clinic; Dr. Olive Rendel conducts the ante-natal cardiac clinic. A part-time anaesthetist undertakes the work in connexion with the gynaecological operations. Recently a resident anaesthetist has been provided for the maternity patients. There is a registrar's clerk for the keeping of case sheets and records, and a typist, who also acts as messenger. The director has a private secretary, who keeps the records of class attendances, prepares the material for lectures and demonstrations, and manipulates the lantern. The pathological and biochemical work of the Unit is carried out in the pathological department under the supervision of Professor Hadfield.

TRAINING OF STUDENTS

Each student has six months' training in gynaecology and obstetrics. Diseases of children are not included, but are taken as an entirely separate course.

Gynaecological Clerks

The students (four to five) spend three months as gynaecological clerks and are not in residence. This training is not confined to the Unit, but may be taken in the gynaecological department of the hospital or in the Elizabeth Garrett Anderson Hospital. The clerkships are whole-time, with the exception of attendance at the V.D. out-patient department.

The teaching consists of a weekly morning round with the director and senior assistants respectively. Each round is followed by a differential diagnosis demonstration in an examination room off the ward. The patients are examined one by one, and the condition is discussed and treatment indicated. This class is held the day before operations, so that the students may be able to verify the diagnosis and follow up the treatment. Patients are not examined, as a rule, in the ward. Each assistant has a certain number of beds allotted to her by the director. The students act as instrument and dressing clerks at the operations. They are responsible for the notes under the supervision of the registrar, and they label and convey the specimens to the pathological department. A special demonstration on gynaecological pathology is given once a week by the director. This is illustrated with specimens and lantern and microscopical slides. The students attend the out-patient clinic one morning and one afternoon under the direction of the director and senior assistants. Two students are in attendance on each examination couch. The students are responsible for the preparation of the notes of the new patients before the teaching begins.

Obstetrical Clerks

All students must take their obstetrical training in the Unit. Twelve students are in residence for three months. A preliminary course of six demonstrations in midwifery is given by the third assistant before the students take up residence.

First Month.—Four students are in attendance in the wards. The third assistant demonstrates the first three labour cases or "show cases." The subsequent cases are taken by the students in rotation. No vaginal examinations are made and no delivery of a patient takes place unless a member of the staff is in the labour ward. The students are provided with sterile gowns and masks, the student who is delivering the patient being also provided with sterile gloves. The sisters of the wards do not undertake the teaching of the students. They are responsible for the cases of the pupil midwife, who receives her training as a scholarship from the hospital board. Only one is trained at a time. No case is credited to the student unless she delivers the patient herself. Operations, such as forceps or Caesarean section, are not counted as students' cases. Only one student counts the case, although others are acting as assistants at the delivery.

Second Month.—At the end of the first month the students take up residence in the Islington Clinic and attend district patients under the supervision of the obstetric officer, who must visit the patient at least once during the confinement or puerperium. Strict rules are enforced as to sending for assistance when any abnormal condition is diagnosed.

Third Month.—The senior students return to hospital and take up the work of the district, and also the delivery of the patients in the V.D. maternity department. This department is under the supervision of the second senior assistant and the district obstetric officer. The director of the V.D. department pays a weekly visit to superintend the carrying out of treatment. All students attend, when possible, the morning teaching rounds. These are held once a week by the director and two senior assistants respectively. Weekly demonstrations are given by the director and senior staff. These consist of questions and answers on clinical obstetrics. The third assistant also has small demonstrations. The junior and senior students attend the three weekly ante-natal clinics and one post-natal clinic at the hospital. The students at the Islington clinic attend weekly ante-natal and one post-natal clinic for the district patients. The septic and suspect ward is

entirely separate from the general maternity wards, and is looked after by the senior staff and gynaecological house-surgeon. The gynaecological students, and not the obstetrical, are in attendance.

Final-year students preparing for examinations are given demonstrations on obstetrics and gynaecology by the director and senior assistants weekly. They also attend the ante-natal clinics. The director gives a lecture demonstration once a week to senior students. Systematic lectures are omitted. Instruction takes the form of demonstrations either in the labour wards or by lantern and phantom. The development of teaching by means of the cinema is being carried out by the director at present.

The chief aim of the teaching in the Unit is the study of normal conditions and the prevention and diagnosis of complications. The adaptation of institutional to domestic conditions is of the utmost importance to students in teaching them self-reliance. Successful midwifery means the expenditure of time and infinite patience, with accuracy of diagnosis. It is the teacher of the undergraduate who is responsible for the future success of a national maternity service.

THE CAMPAIGN AGAINST LEPROSY

INTERNATIONAL CONFERENCE IN MANILA

Under the auspices of the Leonard Wood Memorial for the Eradication of Leprosy, an international conference was held at Manila, in the Philippine Islands, from January 9th to 23rd. To this conference twenty-five members were invited, of whom twenty-three were able to attend. The following is a list of those present at the conference:

Dr. Et. Burnet, secretary, Leprosy Commission, League of Nations; Dr. Robert G. Cochrane, secretary, British Empire Leprosy Relief Association; Mr. H. I. Cole, Ph.D., chief chemist, Culion Leper Colony; Dr. J. Fajardo, Director of Health, Philippine Health Service; Major-General J. D. Graham, Public Health Commissioner, Government of India; Dr. G. Gushue-Taylor, superintendent, Mackay Memorial Hospital, Taihoku, Formosa; Dr. V. G. Heiser, Director for the Far East, Rockefeller Foundation; Dr. Lee S. Huizenga, superintendent, Mission Hospital, Jukao, Ku., China; Dr. A. N. Kingsbury, director, Research Institute, Kuala Lumpur, F.M.S.; Dr. P. H. J. Lampe, Director of Health, Surinam, South America; Dr. C. B. Lara, chief physician, Culion Leper Colony; Dr. J. Lowe, medical superintendent, Dichpalli Leprosy Hospital, India; Dr. James L. Maxwell, Lester Institute of Medical Research, Shanghai; Dr. E. Muir, leprosy research worker, Calcutta School of Tropical Medicine; Dr. A. E. Neff, superintendent, Makogai Central Leper Hospital, Fiji; Professor Nocht, president, Leprosy Commission, League of Nations; Dr. M. Ohta, Tohoku Imperial University, Japan; Dr. J. N. Rodriguez, supervisor of treatment stations, Philippine Health Service; Dr. J. C. Tull, Government pathologist, Singapore, Straits Settlements; Dr. H. W. Wade, chief pathologist, Philippine Health Service, and medical director, Leonard Wood Memorial; Dr. N. E. Wayson, Leprosy Investigation Station, Honolulu; Drs. LeRoy Desbarres and H. Joyeux of French Indo-China.

The conference was unique in that no formal papers were presented. This meant that the whole time was devoted to discussions. Because of the controversial nature of many topics, it was decided that it would be better not to admit the press, lest lay reporters should mistake enthusiasm in debate for violent disagreement. The subjects for discussion were allocated to subcommittees, of which there were eleven. These subcommittees prepared memoranda, which were then discussed by the whole session, and finally incorporated into the findings of the conference. It was no mean achievement for twenty-three men, all with different experiences and with varying points of view, to issue a unanimous report on every subject which was discussed.

SCOPE OF THE CONFERENCE

The comprehensive nature of the findings will be appreciated by a glance at the following headings:

I. *International Viewpoint.*
   Study tours; transfer of workers; leprosy digest or annuaire.

II. *Uniformity of Methods and Terms.*
   1. Designation of cases of leprosy.
   2. Designation of lesions. Definition of macular; acroteric; skin changes; leprotic, leproma, ulcers, infiltration, nodule, papule, macule.
   3. The micro-organism. Nomenclature; toxins.
   4. Clinical classification of cases. Primary classification; proposed classification of types of leprosy; main types, subtypes.
   5. Administrative classification of cases.
   6. Lepra reaction.
   7. Early diagnosis of leprosy.
   8. Methods of examination. Clinical, bacteriological.
   9. Treatment of leprosy.
   10. Evaluation of progress. Definitions of active cases, quiescent cases, arrested cases, cure, relative cure (negative, interrupted, and relapsed).
   11. Follow-up of patients.
   12. Study of contacts.
   13. Standardization of records.

III. *Prophylaxis.*

IV. *Research.*

Appendices.—(1) Details of examination. (2) Method of treatment by intradermal injection. (3) Treatment of lepra reaction. (4) Manufacture of mixed ethyl esters of hydnocarpus group oils. (5) Epidemiological surveys.

SUMMARY OF FINDINGS

The first point which is dealt with in the report of the conference is the importance of an international understanding among leprosy workers. It is pointed out that until recently insufficient appreciation of the fundamental differences in conditions and practices existing in different regions has given rise to a great deal of confusion.

Leprosy has a wide range of manifestations, and local conditions differ to so great an extent that they must determine, in a large measure, the nature of antileprosy activities. Apparent results of treatment are influenced by such features as the type of case, the degree of advancement, and the conditions under which patients come under observation. Because of these varying conditions it is not only highly desirable that leprosy workers should be afforded an opportunity for making study tours, but it would greatly assist progress if some kind of system were organized whereby workers could be transferred from one region to another, so that they might have a better understanding of the conditions prevailing in other countries. The report suggests that the desirability of such a transfer of workers should be brought to the notice of institutions and organizations concerned with the study of leprosy.

Under the heading "Uniformity of Methods and Terms" it will be seen that a large field is considered. It is of the utmost practical importance that terms should be defined, and certain definitions which tend to cause confusion should be omitted. Such indefinite terms as clinical, incipient, infectious, burned-out, should, whenever possible, be replaced by more specific terms. "Burned-out" is more descriptive than accurate, and "arrested with deformity" is substituted.

Under "Designation of Lesions" the various neural and cutaneous lesions are described. This is one of the most important parts of the report, for the terms in common use need international definitions so that they will be understood by all workers. One of the most important definitions is that of "leprotic," which is defined as follows:

> "The term 'leprotic' should be applied to those changes which present clinical or microscopic evidence of inflammatory processes, typically of granulomatous nature, which are apparently caused by the *Mycobacterium leprae* in them. In such lesions the organism can usually be demonstrated by the ordinary methods of examination."

In this a sharp distinction is made between true leprotic lesions and those of trophic or traumatic nature, which are the usual accompaniment of the majority of cases of leprosy. The section of the report on skin lesions and their description should be of great assistance to clinicians generally.

The micro-organism is next dealt with; it is recommended that the name *M. leprae* be adopted, and that *B. leprae* be discontinued. After a short dissertation on the question of the existence of toxins of the disease, the important

subject of clinical classification is then considered. While it is recognized that leprosy is a generalized disease, for the sake of clarity and for clinical purposes two main groups are recognized—namely, (1) neural, (2) cutaneous. It is also acknowledged that the pure cutaneous case rarely exists as such, for even though no clinical signs of neural involvement are present, pathological examination, either by biopsy or necropsy, will reveal nerve changes. The two types are divided into subtypes—namely, N_1, N_2, N_3, or C_1, C_2, C_3, or N_1C_1, N_1C_2, etc.—according to the degree of severity of the disease, and whether neural or cutaneous signs are predominant. Combinations of the two letters are used in those cases where both nerve and skin signs are obvious.

In an important paragraph on administrative classification it is recommended that the old terms "infective" and "non-infective" be omitted, for in rare instances neural cases may be infectious on account of a positive nasal discharge. This classification is being brought more into line with that of tuberculosis, by dividing the cases into "open" and "closed." It is suggested that administrative action may well differ in the two types. The report then deals in a clear manner with the subjects of lepra reaction and early diagnosis and methods of examination.

A long section follows on treatment. It is this section which will be studied most carefully by those whose duty it is to take charge of cases of leprosy. The first point stressed is that no special treatment is likely to succeed unless the general measures are vigorously pursued. The report states that it is believed by physicians experienced in this disease that careful and persistent efforts to eliminate intercurrent affections which tend to reduce the general health of the patient are very essential to successful therapy. Observations suggest that the adjustment of both quality and quantity of the diet may be an important therapeutic measure. It is the belief of those with a large experience that other general measures, including personal hygiene, supervised or graduated physical exercise, occupational therapy, and moral and mental welfare, are also of definite value.

Special measures dealt with are, first, the oils of *Hydnocarpus wightiana* and *Hydnocarpus anthelmintica* (chaulmoogra group) and their derivatives, the chief of which are the ethyl esters of the fatty acids and the soaps (sodium salts) of these acids. No special drugs are definitely recommended, as the choice depends on factors such as the ease with which they are procured, their cost on delivery, their purity, freshness, and keeping qualities. Other drugs mentioned are gold salts and other heavy metals; foreign proteins, and measures such as ultra-violet light, radiant heat, carbon dioxide snow, fulguration, and diathermy, also have their place.

The sections on appraisal of treatment and evaluation of progress are important. Working definitions are given of the terms "active," "quiescent," and "arrested," also an indication of the period of time which should elapse before a case is considered to have passed from the stage of quiescence to that of arrest. As the term "cure" in relation to results of treatment is open to misunderstanding, it is recommended that this should not be used in the terminology of leprosy. Since "negative" is often misinterpreted, and "quiescent" is more descriptive, it is recommended that the latter term be used. For relative cure the word "arrest" is suggested.

The importance of examining persons who have lived in contact with cases of leprosy is emphasized, for the eradication of this disease in any given area may depend largely upon the application of the knowledge so gained. The report lays stress on the need of standardizing the records made by leprosy workers everywhere, and it has been suggested that an organization such as the Leprosy Commission of the League of Nations might well take up this matter. The question of leprosy research is dealt with at some length, and many suggestions are made concerning the direction which such research should take. The epidemiological problems are given special prominence, and this section of the report will serve as a useful guide to those who are doing leprosy research work.

FORMATION OF INTERNATIONAL ASSOCIATION

Possibly the most important action taken by the conference was the formation of an International Leprosy Association, the purpose of which is to encourage and facilitate collaboration between persons of all nationalities concerned in leprosy work, and the co-ordination of their efforts, to promote the dissemination of knowledge of leprosy and its control, and in any other practicable manner to aid in the antileprosy campaign throughout the world. For the period of organization the following temporary officers were elected:

President, Dr. Victor G. Heiser; Vice-President for the Western Section, Professor Carlos Chagas of Brazil; Vice-President for the Eastern Section, Dr. Ernest Muir of Calcutta; General Secretary, Dr. Robert G. Cochrane of London; General Treasurer, Mr. William H. Brown, Ph.D., of Manila. Sir Leonard Rogers of London, Dr. Etienne Burnet of the League of Nations Secretariat, and Professor de Langen of Batavia are General Councillors.

One of the most important activities of this association will be the issue of a *Journal of Leprosy*, which will endeavour to publish articles on every aspect of leprosy, and so make an outstanding contribution towards the unification of leprosy work. Dr. H. W. Wade has been appointed temporarily as editor, with Dr. Lie of Norway and Dr. Maxwell of China as associate editors.

It is hoped that a large amount of support will be forthcoming from medical men interested in leprosy, for only through collaboration and co-operation can progress be maintained, and further opportunities such as the Manila Conference be afforded for mutual discussion on international lines. The Far Eastern Association of Tropical Medicine has become an established institution, and those interested in research and progress in leprosy are urged to combine to make this new association an outstanding success. Inquiries should be sent to the secretary at 29, Dorset Square, N.W.1.

Printed copies of the full report on the conference will be available shortly, and those desirous of obtaining them should apply to the British Empire Leprosy Relief Association at the address given above.

ROBT. G. COCHRANE.

England and Wales

Motor Ambulance Service in Wales

The Priory for Wales of the Order of St. John has reduced the charges for the use of its motor ambulances by non-subscribers from 2s. to 1s. 6d. a mile, with a minimum fee of 10s. 6d., instead of £1 1s., up to seven miles; and the charge for waiting time has been reduced to 5s. an hour from 10s. This announcement is of no little importance, because the Priory's motor ambulance transport service has become an indispensable factor in the public life of South Wales. The provision of ambulance transport was one of the earliest aims of the Priory, and a scheme was evolved in 1918 under which colliery lodges and bodies of workmen were invited to subscribe at the rate of one penny per man per week for the free use of an ambulance for himself and any member of his household in case of accident or sickness; and colliery companies were given an opportunity of contributing 1s. per man per annum for the removal of injured workmen. The advantages of subscribing to an efficient service of interchangeable cars in comparison with the upkeep of one ambulance were readily perceived, and the Home Office agreed that any colliery company subscribing to the Priory's service would be deemed to be complying with the regulations regarding the provision of ambulance transport. There are to-day seventy-five colliery and other companies under contract with the Priory; and fifty-six colliery lodges are affiliated, whilst thirty-three other

bodies of workmen and townspeople are subscribing at the rate of one penny a week. Cars are stationed at Ammanford, Bryn, Cardiff, Coedely, Cross Keys, Cymmer, Gwaun-cae-Gurwen, Kenfig Hill, Llanbradach, Llanelly, Pencoed, Pontardulais, Pontypridd, and Tumble, with a central garage and relief cars at Cardiff. During 1930 three stations were opened, each new car adding a further link to the increasing chain of ambulances which the Priory hopes, with the support of the colliery owners and workmen, to extend over the whole coalfield. These cars are maintained in day and night commission, in charge of whole-time drivers—qualified ambulance men—and are available for all sections of the public. Innumerable cases are carried at reduced charges or free of cost, as, although the service has been established and maintained at a great cost, the primary aim is to enable the sick or injured, irrespective of means, to be brought speedily and without undue suffering within the scope of medical and surgical aid. The Priory is endeavouring to make the extension of these provisions keep pace with the growing demand consequent on the ever-increasing number of accidents.

British Legion Village at Preston Hall

The annual report of the medical director of the British Legion Village at Preston Hall, Aylesford, Kent, covers the eighteen months ending September 30th, 1930. The community now numbers 770. During the period under review 446 patients were admitted to the sanatorium, and 407 discharged, of whom 94 were fit for ordinary work and 123 fit for some modified work adapted to their clinical condition. The tuberculosis statistics are not comparable with those of sanatoriums elsewhere, because the majority of tuberculous ex-service men are ageing out of all proportion to their years; the tuberculous pensioner is rapidly disappearing, and it is rare to find one admitted for treatment who is not suffering from extensive bilateral disease. The number of cases receiving treatment in the sanatorium at any time remains about 180, and, as the years pass on, the numbers available from so limited a section of the population will dwindle; local authorities are therefore being invited to send dependants of ex-service men for treatment. Routine visits are paid to houses in the village as part of the preventive mechanism which is so essential in settlement work. *X*-ray examinations are made systematically of the children of tuberculous parents, but so far very little evidence of infection has been detected even in this way, and during the past five and a half years no infants have developed tuberculous meningitis in the community at Preston Hall—one of the indications that this settlement is operating effectively as a preventorium for children. A new child welfare centre is being instituted. The difficulties of finding employment for patients discharged from the sanatorium are being tackled, but it is recognized that it is impracticable for village settlements to absorb these persons in the numbers in which they present themselves. The resources of the different charitable organizations are proving very valuable in this connexion. As a trading concern Preston Hall has prospered well of late; the thrift club has over £800 to distribute at Christmas each year, and efforts are being made by many parents to provide higher education for their children. As a social as well as a medical experiment, Preston Hall has justified the interest taken in it by the British Legion, and it is approved by the Ministry of Health. The cost of treatment is £2 12s. 6d. per patient per week. The Legion pays the travelling expenses of patients, whether ex-service or dependants, sent by authorities outside the Home Counties. Forms on which such persons may be recommended for treatment are obtainable from the medical director, Dr. J. B. McDougall.

Staffing of Laboratory Services under the London County Council

The pathological laboratory services to be provided for the hospitals transferred to the London County Council under the Local Government Act, 1929, have been the subject of lengthy consideration by the Central Public Health Committee. There were transferred to the Council from the Metropolitan Asylums Board, the Northern Group, and Southern Group laboratories (located at the North-Eastern Hospital and at Park Hospital respectively), where complex and special work which cannot be dealt with at the ordinary laboratories is carried out, and also a special laboratory at Belmont, at which serums are prepared. The committee considers that the director of the antitoxin establishment at Belmont and the directors of the Northern and Southern Group laboratories should have a salary of £1,100 a year, rising by annual increments of £50 to £1,300. The bacteriologist or deputy director at Belmont is to have a salary of £800, rising by £50 to £1,000, and the biochemist £700, rising by £25 to a maximum of £900. At the Northern and Southern Group laboratories the scale for the assistant director is to be £750, rising by £25 to £900, and for the assistant pathologist £650, rising by £25 to £800. Five group laboratories are to be established at selected hospitals, capable of dealing with a certain amount of specialized work. The pathologist in charge of each of these laboratories is to have a salary of £1,100, rising by annual increments of £50 to £1,300. To serve the group laboratories a histological branch will be required, and the remuneration of the histologist is to be £1,000, rising by £50 to £1,200. It is proposed to set up a special grade of women laboratory technicians for the service of these laboratories, obtaining recruits by the selection of girls of good education, not less than 18 years of age, who have specialized in science at a secondary school.

Queen's Hospital, Birmingham

The annual meeting of the governors was held on April 1st. Considerable concern about the financial state of the hospital was shown by several speakers. The Lord Mayor, presiding, said that he learnt with dismay that the working expenses for 1930 were £12,000 in excess of income. The chairman of the Committee of Management informed the meeting that, unless £3,800 was found by the end of June, a ward of twenty-four beds would have to be closed on July 1st. This state of affairs had arisen, said the honorary treasurer, because, in order to further the Hospitals' Centre Scheme, appeals for public support for the hospital had not been issued. It was pointed out by Professor Emanuel that, although the Hospitals' Contributory Scheme was increasing its income each year, the General and the Queen's Hospitals had had to limit their activities on account of lack of funds. Professor W. Billington urged that money should be set aside for laboratory and research work, so that the public obligations of a teaching hospital in advancing medical knowledge might be fulfilled.

Central Midwives Board

At the April meeting of the Central Midwives Board for England and Wales, Dr. J. S. Fairbairn was elected chairman. A letter was read from the Ministry of Health stating that the Minister had approved, for the purpose of appointment, the balance against the Board of £4,861 13s. 6d. for the year ended December 31st, 1930. It was announced that Dr. T. Vincent Dickenson had been re-elected as representative on the Board by the Society of Apothecaries of London, and that the following had been appointed members of the Approvals and Examination Subcommittee: Mr. Comyns Berkeley, Dr. W. Allen Daley, Miss A. Davies, Miss E. M. Doubleday,

Miss E. E. Greaves, Councillor W. J. Loxley, Miss A. A. I. Pollard, and Mrs. Elena Richmond. The list of examiners, as submitted for the year ending March 31st, 1932, was approved, as were also the amended list of lecturers, and the institutions, homes, and midwives at which, and under whom, midwives may be trained.

Ireland

Medical Benefit in Northern Ireland

Mr. J. M. Andrews, Minister for Labour, recently stated in the House of Commons of Northern Ireland that 476 doctors and 399 chemists were participating in the medical benefit scheme, and that only three complaints had been received by the department in reference to the service provided for insured persons. This, he thought, was a very gratifying result. Since the introduction of medical benefit there had been a fall in the demand for sickness benefit, due partly to skilled treatment at an early stage of disease. As about one and a half million records and other documents had to be prepared he thought that those engaged in this work deserved credit for the way in which they had brought this service into existence.

Goitre in Northern Ireland

Dr. R. Olesen and Dr. P. A. Neal have contributed an interesting note to the United States Public Health Reports on the incidence of endemic goitre in Northern Ireland. Between July, 1929, and June, 1930, they examined 8,640 Irish emigrants, of whom 4,648 were men and 3,992 were women. Nearly all of these came from Ulster. Enlargement of the thyroid was found in 552 men (11.8 per cent.), and in 1,095 women (27.4 per cent.). By enlargement of the thyroid the authors mean anything from a very slight enlargement to definite adenoma; and as 9.4 per cent. of the men and 16.3 per cent. of the women come under the heading of "very slight" enlargement, the statistics may give an exaggerated idea of the incidence of "goitre" in Northern Ireland. The figures indicate that the greatest number of cases in females occur between the ages of 15 and 19, and in males between the ages of 20 and 24.

Vital Statistics for the Irish Free State

During the quarter ending December 31st, 1930, 13,717 births were registered in the Irish Free State, this number representing an annual birth rate of 18.6 per 1,000 of the estimated population. The equivalent figure for Northern Ireland was 19.6, for England and Wales 15.4, and for Scotland 18.8. The rate in the Irish Free State is 0.1 below the rate for the corresponding quarter of 1929, and 0.3 below the average rate for the fourth quarters of the ten years 1920 to 1929. Deaths registered during the quarter numbered 9,836, or an annual rate of 13.4 per 1,000. This rate is 0.3 above the rate for the corresponding quarter of 1929, and 0.1 above the average rate for the fourth quarters of the preceding ten years. Of the deaths registered, 969, or 9.9 per cent., were those of infants under 1 year, the number of deaths of infants being equivalent to 71 per 1,000 births, compared with 79, 67, and 52 for the three previous quarters. Deaths from tuberculous disease numbered 780, or a rate of 1.06 per 1,000, and deaths from cancer 767, or a rate of 1.04. The average mortality rates for these diseases for the fourth quarters, 1927 to 1929, were 1.15 and 1.11 respectively. The urban mortality from the principal epidemic diseases recorded during the quarter was equivalent to an annual rate of 1.2 per 1,000 of the population, the death rate from these diseases being 0.3 for the remainder of the Irish Free State. Included in the returns is a detailed statistical summary of births and deaths relating to the twelve principal towns and other urban districts in the Irish Free State for the year 1930.

Legislation for Clean Milk

In a letter to Sir James Craig (Dublin University), the Minister for Local Government and Public Health explains that the delay in introducing legislation in regard to the milk supply has been caused by lack of parliamentary time. Since October, 1929, consideration has had to be given to the Local Government (Dublin) Bill, the National Health Insurance Bill, and to Bills on housing and poor relief. While recognizing fully the importance of early legislation on milk, the Minister states that he does not consider that the above mentioned Bills could have been postponed. He affirms that he will do everything possible to have the desired legislation expedited during this session, but points out that there are also urgent demands for Bills relating to road traffic, electoral redistribution, town planning, and housing. Replying in the Dail to a question on the same subject from Dr. T. Hennessy (Dublin City South), the Minister stated that he was unable at present to introduce legislation dealing with the matter.

Correspondence

EMPYEMA THORACIS

SIR,—The two recent communications in the *Journal* on the subject of empyema thoracis are important, emphasizing as they do fundamental principles on which treatment must be based. For a proper assessment of these, however, there are some further facts which have to be kept in view, and which, I think, are not given full weight in these papers (particularly Dr. Burrell's), although I am in full agreement with the main tendency of their conclusions. The calculations regarding the size of opening in the chest wall compatible with life assume a perfectly mobile mediastinum. In practice this probably never occurs. Even in healthy animals these theoretical considerations do not apply *in toto*. War experience showed, not that open pneumothorax was incompatible with life, but that a "sucking wound" of the chest led to a pneumothorax with a constantly rising intrapleural pressure and an early fatal result.

It is easy to talk of "sterilizing" the cavity. This is very difficult to accomplish. Attempts to do so by washing out the cavity in the early stages of a streptococcal empyema are, I believe, actually dangerous, as they tend to spread infection and interfere with the formation of adhesions. In a chronic empyema conditions are quite different.

There is, lastly, a point mentioned by Mr. Morriston Davies which needs reiteration. The majority of cases of chronic empyema sinuses are due, not to errors of technique or infection of cut ribs, but to the fact that when the surgeon is called in there is already a cavity with rigid walls, which can be collapsed, if at all, only with great difficulty. The treatment is prevention, by earlier exploratory puncture and by institution of the correct treatment, whether that be by the open or the closed method.—I am, etc.,

Liverpool, April 11th. JOHN T. MORRISON.

EMPYEMA THORACIS: OLEOTHORAX AND GELATINOTHORAX IN TREATMENT

SIR,—Mr. Morriston Davies, in his excellent and illuminating article on empyema thoracis in the issue of the *British Medical Journal* of April 4th, deals very fully with aspiration, suction drainage, and operation in the

treatment of this condition. In his concluding paragraph in the section on aspiration he observes that: "In the majority of cases further measures are needed, but an open pneumothorax . . . is not advisable if there is a chance that the empyema can be cured by some other method . . . for example, by siphon or suction drainage." He does not mention the treatment of the condition by the intrapleural injection of antiseptics. These undoubtedly may prove of great value, and should be given a trial before undertaking any procedure which may very easily lead to mixed infection, and thus make a bad case still more serious. There are two forms of intrapleural injections which have proved of particular value: oleothorax and gelatinothorax.

Oleothorax was introduced to the profession in 1921, and has been much used, particularly by Continental workers. An 8 to 10 per cent. preparation of gomenol in olive oil or liquid paraffin is employed. When olive oil is used it is sterilized at 105° C. for an hour and a half. When liquid paraffin is used it is sterilized at 150° C. for twenty minutes. The gomenol is added after sterilization. Messrs. Wilcox, Jozeau, and Co., London, I believe, market the preparations ready for injection. The prepared oil is heated to 38° C. on a water-bath immediately before use, to facilitate its introduction. At the first injection, to test the susceptibility of the individual, 5 to 10 c.cm. only are introduced into the pleural cavity. If there be no marked reaction, as much as 400 to 500 c.cm. may be injected in the course of four or five days after the removal of the fluid and its replacement by gas. Further injections may be given every four or five days until the pleural cavity is filled up with the fluid. The action of the gomenol is not merely that of an antiseptic; it has a congestive effect on the pleural membrane, which determines a flow of polymorphs to the part. According to Bernou, these polymorphs produce a ferment which has not only a proteolytic but also a lipolytic action. This results in an intensification of the antiseptic properties of the injected oils.

Gelatinothorax is a technique of great promise in the treatment of empyema. It has been developed at the Consumption Sanatoria of Scotland, Bridge of Weir, during the past year, and consists of the injection of a 2 to 5 per cent. preparation of gelatin, in which there is dissolved 1 in 2,000 to 1 in 5,000 acriflavine. This may be prepared according to the process described by R. A. Hunter in *Tubercle*, February, 1931. It may more readily be made up from sterules of concentrated gelatin in normal saline, such as are sold by Messrs. Martindale of London. Sterile water is added to the contents of one of these sterules as directed, and that gives 5 ounces of a 2 per cent. solution of gelatin in normal saline. Larger-sized sterules are obtainable. Tablets or sterules of euflavine (neutral acriflavine) may also be obtained, which can be rapidly dissolved in this solution of gelatin, in order to give a concentration of 1 in 1,250 to 1 in 5,000 acriflavine in the gelatin solution, as may be required. As acriflavine is an aniline dye, it is advisable to mix the gelatin and the acriflavine together just before use, rather than to have the two together as a stock preparation. The technique of treatment is very simple.

Of the purulent material in the pleural cavity 20 c.cm. is removed with a syringe having a two-way stopcock, and this is replaced by 20 c.cm. of the gelatin-acriflavine preparation, which has been previously heated to 100° F. If there be no febrile reaction, at intervals of two or three days increasing quantities, up to 300 or 400 c.cm., of purulent fluid are removed and replaced by gelatin and acriflavine. No more should be added than is necessary to sterilize the purulent collection in the pleural cavity. This will evidence itself mainly by the clearing up of the symptoms. The gelatin preparation mingles intimately with the fluid in the pleural cavity and converts the pleural sac into a vessel filled with an antiseptic solution.

As Dr. Lawrence P. Garrod points out in the same issue of the *British Medical Journal*, acriflavine is an antiseptic which has "the property of exerting a bacteriostatic action in enormous dilutions"—very much greater than that of any other commonly used antiseptic. As Browning, who introduced acriflavine, has demonstrated, acriflavine has an enhanced value as an antiseptic in the presence of serum. If, because of susceptibility of the patient to the drug, reactions show themselves, aspiration of the fluid and its replacement with air causes the symptoms to pass off. The temporary presence of the antiseptic seems to exert a beneficial effect in every such case in our experience. A number of cases could be instanced where this simple procedure has had a definite and apparently permanent beneficial effect on pleural fluid which had become septic or which showed numerous tubercle bacilli. In one or two cases of open pneumothorax in which operation could not be performed, repeated injections have so cleaned up the pleural cavity as to make successful operative procedure possible.

In my opinion oleothorax or gelatinothorax should always be tried in cases of empyema before siphonage, suction drainage, or operation is considered. Of these two measures, gelatinothorax is to be preferred.

Many early workers in bacteriology, including Koch, demonstrated that aniline dyes had a selective action on the various classes of bacilli—bacteriostatic or bacteriocidal. Practical application of this has been found in the laboratory in the isolation of organisms such as the typhoid bacillus. Churchman showed that Gram-positive organisms were susceptible to gentian violet and Gram-negative organisms to acid fuchsin, and used gentian violet successfully in closed cavities and in joint affections. The action of the dyes in pyogenic conditions he characterized as bacteriostatic rather than bactericidal. Even weak dilutions had considerable power of penetration.

Many workers have used aniline dyes in the treatment of septic effusions in the pleura. I have had several cases during the past fifteen years which responded very satisfactorily to repeated lavage with brilliant green, using a 1 in 3,000 dilution. The pleural cavity was filled up with this and thereafter emptied. This was repeated until the solution was returned as it had been put in, and at the end 200 to 300 c.cm. of the solution was left in the pleural cavity. This procedure had to be resorted to every two to five days, and was slow and somewhat painful, although productive of good results. The gelatin-acriflavine technique more recently adopted is simpler and much more rapid. Lavage is not called for, though aspiration may be required. The method has of course not been long enough in use to enable one to speak of permanent results. One can but reiterate that it promises very well.

If an empyema can be cured by some method that does not involve the risk of an open pneumothorax, that should be given a trial. This letter is a plea for intrapleural injections, particularly gelatinothorax.—I am, etc.,

Glasgow, April 10th. JAMES CROCKET, M.D.

HALLUX VALGUS

SIR,—I should like to add my testimony to that of Mr. James Phillips and Sir Charters Symonds as to the excellent results of the operative treatment of hallux valgus and hallux rigidus by the method they recommend—namely, the removal of the proximal part of the first phalanx. I published in the *Clinical Journal* of March 5th, 1930, a plea for its general use, with a full discussion and details of the operation. The tripod of the foot is preserved. The after-treatment has the merit of being extremely simple, no extension of the toe and no massage

being necessary, nor any plate to support the anterior arch. The results are uniformly good, and admit of the normal performance of army route marches or police gymnastics, or of the full enjoyment of dancing, after the bilateral operation.—I am, etc.,

Bradford, April 11th. PETER MCEWAN.

THE CANFIELD OPERATION FOR PARANASAL SUPPURATION

SIR,—Sir James Dundas-Grant, with Dr. Perry Goldsmith, is an advocate of the Canfield operation for drainage and instrumentation of the maxillary antrum. Any observations that Sir James makes must be treated with respect. His reasons for this operation are twofold:

1. That the opening, whether small or not, lies far forward in the nasal cavity, and therefore nearer the open air.
2. That it is situated in a narrow part of the passage, so that the current of air going past it in respiration acts on the antrum like wind over a chimney.

May I be allowed to bring, as briefly as I can in a letter, some argument against the claims of this operation? An operation to be a success must be based on physiological grounds. It would appear to me that Canfield's operation is opposed to the proper function of the nasal sinuses, for the following reasons.

The nasal sinuses, in my view, are expiratory cavities. With the exception of two openings—namely, the sphenoid and Eustachian tube, which are not nasal sinuses—all the ostia look towards the post-nasal space. Moreover, if a disc of bone is removed from the anterior wall of the frontal sinus it will be noticed that, during expiration, the lining membrane bulges, and on inspiration it is sucked in. It is upon this proper functioning that facial symmetry largely depends. In anterior block of the nares in children there will be no asymmetry. With a block about the middle of the nares, interfering with proper aeration of the sinus, facial asymmetry results. Physiologically it is incorrect to make an anterior opening into the antrum.

If the lining membrane is polypoid, a radical operation, such as the Caldwell-Luc, is the efficient one. If drainage is all that is required, an opening should be made through the inferior meatus a little behind the middle line. The difficulty I used to encounter in making my opening was to form one which would remain patent. This led to imperfect drainage and douching. To overcome this, Messrs. Mayer and Phelps have made for me an instrument which, with a powerful pair of punch forceps, has completely met the difficulty. Nevertheless, unless a suitable lotion is used for douching, the purulent condition remains, and the patient has periodic outbursts of illness. Having been a sufferer from this condition myself since I was on active service in 1916, it is a great relief to me that I have, after many trials, succeeded in concocting a lotion which seems to have conquered this, and which does no harm to the mucous membrane of the nares.—I am, etc.,

Maidstone, April 4th. J. ALDINGTON GIBB.

CONVULSIONS DURING SURGICAL ANAESTHESIA

SIR,—Diacetic acid and acetone are found in the urine in a considerable percentage of all surgical cases in children. Much less frequently they are found in adults. This result of incomplete metabolism arises in the subjects of operations of election as well as emergency operations, and in non-septic as well as in septic cases. Dr. Louise Fraser suggests (*British Medical Journal*, March 28th, p. 562) that ketosis may have been one of the toxaemic factors in the etiology of these convulsions. Ketosis readily occurs in the presence of suppurative processes, and may be a contributory or aggravating element, but in my opinion the primary and essential condition which gives rise to these convulsions is acute sepsis and toxaemia, to which the organism has not had sufficient time to develop defences. The administration of carbohydrate to surgical patients in my own practice is carried out on these lines: adults have one teaspoonful of glucose three times a day, children are given barley sugar *ad lib.*, and infants have frequent sips of sweetened water before and after operation.—I am, etc.,

Aberdeen, April 3rd. J. ROSS MACKENZIE.

VACCINE DOSAGE

SIR,—I sympathize with Dr. Harold Balme in his complaint against the varying dosage of streptococcal vaccines suggested by different pathologists (*British Medical Journal*, April 4th, p. 604). At the same time I think that his case is a little weak. Vaccine dosage is assessed usually on such factors as the patient's weight, his age, his past history of reaction to vaccines, and present condition, and unless the four cases are exactly comparable in all these respects his plea falls to the ground. Again, the types of streptococci vary, the haemolytic types being more active than the others, so that lower doses are generally necessary. Methods of standardization vary in accuracy, but are generally sufficiently comparable. The usual experience is that a trial dose or two has to be given to estimate the patient's resistance to dosage; the dose is then regulated so as to produce a mild reaction. It is up to the practitioner to try the vaccine out, and afterwards to have the strength lessened or increased, according to results. In my experience there are no fixed rules in this matter. It is a question of assessing the various factors and then trying out.

This brings out very clearly the real need for close co-operation between pathologist and practitioner. If he is to produce a satisfactory vaccine the pathologist should have all clinical data and the patient before him. I might add two instances of what happens if there is insufficient clinical assistance. I was criticized because an autogenous vaccine from the sputum failed to clear up a catarrh. The patient was subsequently found to have a neoplasm of the lung. In another case, undetected nasal polypi caused an autogenous catarrhal vaccine to be a "wash-out." The day of water-tight compartments is over.—I am, etc.,

Eastbourne, April 7th. A. GEOFFREY SHERA, M.A., M.D.

THE POST-INFLUENZAL COUGH

SIR,—Once again every practising physician has had his life made a burden to him by the persistent irritating cough which follows to a greater or less extent after influenza. Years ago—early in 1918 to be exact—the fact that the main lesion in influenza was an acute tracheitis was borne in upon me when I happened to compare the tracheae of men who had died from mustard gas poisoning with those who had succumbed to influenza. The similarity was striking—in fact, one could not distinguish between them. The acute congestion began below the larynx and extended down the whole length of the trachea to reach a climax at the bifurcation, where the mucosa was often purplish in colour, with small pin-point erosions scattered over it. Of course I do not imagine that in an ordinary case of influenza one would meet with this degree of inflammation, but I do most strongly maintain that the commonest pathological change in influenza is an acute tracheitis. Granted that this is so, it is easy to understand what happens in influenza. A very short time after exposure to infection the unfortunate individual

feels an uncomfortable sensation low down in his throat—a hot tickly feeling—and soon he demonstrates the effects of influenza toxin and its peculiar temperature. If he is a sensible man he at once retires to bed and sends for his medical attendant, who diagnoses the complaint and, shall we say, injects S.U.P. 36, orders bovril and toast with lots of fluids and so on, and gives some antipyretic. Personally, I have tablets made up consisting of 2 grains of pulv. ipecac. co., 1½ grains of aspirin, and 1½ grains of amidopyrin; I give two at 4 p.m., two at 6 p.m., and two at 8 p.m., with very beneficial results.

So the patient gets over his febrile attack, but there remains a typical cough, paroxysmal in character, always coming on when lying down in bed at night or when going from a warm area to a cold one; in other words, whenever cold air is inhaled over the congested tracheal mucosa. Once a patient starts coughing he finds it very hard to stop. One of my patients, a boy, started to cough at 8 p.m. and finished at 6 a.m. Further, the intensity of the cough varies with the individual; the short, stout-necked person gives a most alarming display, with his empurpled visage, bulging, bloodshot, and streaming eyes, and, whenever he has any breath to spare, his objurgations; but whatever the degree of the paroxysm it is a great nuisance to the owner and to the audience. It bears a startling resemblance to that of whooping-cough, and I have often been asked if I am quite sure that it is not the latter disease.

Now for the treatment of the condition. It is, to be quite frank, disappointing; the ordinary expectorants and the whole extensive group of morphine-heroin remedies spoil the appetite and practically do no good at all. Non-irritating steam inhalations—for example, friar's balsam—are soothing, but anything containing menthol, etc., has naturally just the opposite effect. Counter-irritants to the trachea—camphorated oil, iodine, musterol, linseed poultices, and antiphlogistine—can all be tried; but the only external remedy that does any good is the mercury vapour lamp, which is a most useful line of treatment, and should always be employed whenever possible. The internal remedy has to be a definite antispasmodic, and I find bromoform the best; for children I use the syr. bromoform co. (*B.P.C.*), one teaspoonful morning and afternoon and a dessertspoonful at bedtime, while for adults the elixir bromoformi, one teaspoonful three times a day, is employed with, in severe cases, an allonal tablet at bedtime as well. This treatment certainly makes life more endurable for the patient; but I always impress on him the fact that the cough cannot be cured in a few hours, that it will go on for a while, but that the paroxysms will become less frequent and less severe, that he is not to be frightened about it, as it has nothing to do with the lungs, and that there is no necessity to stay indoors once convalescence is established. Where possible, finances and weather permitting, a change of air is always to be advised.—I am, etc.,

Sydenham, S.E 26, April 10th. G. RICHARDSON, M.D.

LIVER THERAPY IN ASTHMA

SIR,—The *Epitome* of March 28th (para. 295), quoting Matzger (*Journ. Amer. Med. Assoc.*, January 10th, 1931), mentions a case of asthma intensified by ingestion of liver. Last year I tried this treatment on four asthmatics by way of experiment because there is evidence of defective action of the liver in asthma, but with doubts as to the possible benefit, since: (1) both in asthma and after ingestion of liver there is eosinophilia; (2) there is often already erythrocytosis in asthma; and (3) the usual test dose of 15 grams of urea raises the eosinophil count in asthmatics, and may produce severe status asthmaticus. In three of the four asthmatics liver made the asthma worse; it seemed to benefit the fourth, who, however, had only 5 per cent. eosinophils. The disappointing results are only such as might have been expected by anyone familiar with the effect of the urea test in asthmatics. So far as the liver is concerned with haematopoiesis, it is not that function which lags in asthma.—I am, etc.,

Hamilton, Lanarkshire, April 7th. JAMES ADAM.

PRIMARY TREATMENT OF CARBOLIC ACID POISONING

SIR,—The article on carbolic acid poisoning, by Professor O. S. Gibbs, in the *Journal* of April 4th, recalls my experience of immediate contact with severe cases many years ago. Professor Gibbs advocates the use of medicinal liquid paraffin, both externally and internally. In the latter case he recommends a dose of half a pint, or "as much more as one could induce the patient to take." It is easy to understand how paraffin could be confused off-hand with the true oils—that is, with oils of vegetable or of animal origin—but it is important, clinically, that the error should be recognized. Carbolic acid, whether in the form of phenol or of the mixed cresols, is practically insoluble in paraffin in the presence of water. Phenol, for instance, is only soluble to the extent of 1 in 100 of *B.P.* liquid paraffin and 5 in 100 of ordinary vaseline, while in water the solubility is 8 in 100, and in olive oil about 30 in 100. If equal parts of phenol, water, and paraffin are shaken together and allowed to settle overnight, a layer of paraffin will be found at the top practically unaltered in volume or in composition, a layer of phenol at the bottom containing about 40 per cent. of water, and a layer of water in between containing 8 per cent. of phenol. If the experiment is repeated, using castor oil in place of paraffin, two layers only will be found: a water solution of phenol, with castor oil in emulsion, floating on a solution of castor oil, and a little water, in phenol.

Why is it inferred that paraffin forms a protecting layer, or allays irritation, over the surfaces of the stomach and small bowel? It could only be expected to do so if the tract was first emptied. After filling up with normal contents and the resumption of normal movements the paraffin would enter into the general emulsion. Presumably paraffin is eliminated at the same rate as the other contents up to a section of the colon where the dehydrating process is well advanced. At this point part will be expressed by the consolidating contents and serve to lubricate the distal half of the colon and the rectum, and part will serve to maintain the state of emulsion, thereby increasing the normal water content in the stools and rendering them soft. It is claimed that paraffin exerts a mild laxative action in the small bowel; but this would be a small excuse for administering it in the emergency of carbolic poisoning. The heroic dose of half a pint or more might conceivably embarrass the absorbing glands and impair the nourishment of an already damaged system. If carbolic has been swallowed we may eliminate much of it by emesis, or by the wash-out tube, in the more fortunate cases; and we can hinder absorption and encourage secretion by magnesium sulphate; but nothing which we can administer reasonably will remove the poison from moist tissue already penetrated, however superficially. If there was carbolic still floating about in the stomach, as there might well be some considerable time after swallowing disinfecting fluids of the sheep-dip variety, it is clearly best to get rid of it by thorough lavage without wasting time in what would probably be an unsuccessful attempt to immobilize the poison in any oil.

With regard to external injury, poisoning and severe "burns" may be avoided by persistent mopping with castor oil, which removes much of the carbolic from loose association with precipitated protein material. In the days when I was a manufacturer of carbolic acid and tar products I had splashes of melted phenol twice in one eye, and a mixture of cresols and creosote in the other. These were bathed promptly with castor oil, as well as the rapid oedema of the lids would allow, and on each occasion almost all signs of injury passed off within ten days. Frequently workmen were splashed with crude carbolic from buckets suspended below the taps of overhead tanks, etc. Experience taught us the urgent need for thorough treatment when the neck, axillae, groins, or thighs were soaked. The man was rushed off to a drying room, where the temperature induced profuse sweating within a few minutes. A large stock of castor oil and clean rags was always kept in this room. The skin was repeatedly mopped over by fresh relays of warm oil and rags, while large drinks were given of tea, water, or milk. The only stimulant used, as such, was sal volatile. Not until this routine treatment had been carried out was it judged safe to take the man home and summon his medical practitioner. There were no fatal cases of accidental poisoning by carbolic since the works were founded in 1866. Those who have dutifully absorbed the textbook traditions may be shocked to hear that when we were splashed about the hands, arms, or face we turned at once to soap and water, and applied castor oil to the dried parts afterwards. But this was done within seconds rather than minutes. Soft soap is one of the very best solvents for carbolic. We objected most to cresol hot from the still, and were least concerned about pure phenol splashes. The various lysols, disinfecting fluids, sheep-dips, creosotes, and other vehicles of carbolic; each had their relatively better points and objections, and slightly different methods of removal. Perhaps we established a large measure of immunity. One man retired in ripe and healthy old age who had spent most of his working days in an atmosphere of warm phenol vapour. I remember debating with him whether beer or "bolic" had done him most good. It was the same man who told me that one of his friends was eating large meals of sheep's kidney fat for "sores in his bowels." But then, there is a long geological epoch between paraffin and kidney fat!

The use of liquid paraffin internally in cases of carbolic poisoning would be a waste of precious time, and if it was used externally, for the purpose of eliminating the poison, lives would be lost which might have been saved. It is not within my province to deal with secondary treatment for poison already absorbed into the system, beyond suggesting that the intravenous injection of sodium sulphate might well be life-saving in selected cases.

I would summarize my suggestions for primary treatment as follows:

1. For external application in carbolic acid poisoning persistent mopping with warm castor oil. The oil is rather viscous normally, and its solvent powers rise rapidly with the temperature.

2. If castor oil or other suitable oils or fats are not available within a few minutes, do not hesitate to use plenty of soap and a little warm water, applying castor oil dressings later.

3. If the poison has been swallowed, the wash-out tube, using plain water should be used, unless strongly contra-indicated.

4. Give full doses of magnesium sulphate and sodium sulphate together, whether the poison has been applied externally or has been swallowed.

—I am, etc.,

St. Thomas's House, S.E.1, April 7th. W. A. BOWDLER.

"PREPARATION FOR MARRIAGE"

SIR,—It is, I think, fairly widely known that in addition to direct propaganda on the medical aspect of problems of social hygiene and the prevention of venereal disease, the British Social Hygiene Council has given considerable study to the broader problem of preventive education. For some years the approach to the adolescent was a matter of study, and, as a sequel, approved courses of lectures are now being given under the aegis of the Consultative Committee for Youth to leaders of voluntary organizations, and to young people between the ages of 16 and 20. This programme immediately brought to light the need for a further step—that of direct teaching on "preparation for marriage" and the hygiene of marriage.

The council recognizes that in unhappy marriages and broken homes are found the causes that contribute to those practices which lead ultimately to the dissemination of venereal disease, and that any educational measures that can be taken that will reduce the amount of maladjustment within marriage will necessarily tend towards the reduction of the condition with which the council is particularly concerned. For some months a special committee, on which serve prominent technical experts, have studied the method of approach and considered the type of information that should be in the hands of leaders of the community. As a result of these deliberations, arrangements are being made for an experimental course of lectures to be given by members of the committee concerned to selected audiences of leaders in the fields of religion, education, and medicine. The audience is invited to act as a consultative committee to participate actively in the discussion following the lectures, the objective of the course being ultimately the production of a handbook for leaders.

The council wishes to extend a cordial invitation to medical men and women interested in this subject to attend the lectures and give the council the benefit of their advice and suggestions. Full particulars will be forwarded on application to the secretary, the British Social Hygiene Council, Carteret House, Carteret Street, Westminster, S.W.1. The lectures will take place at this address on Tuesdays, at 5.30 p.m., from May 5th to June 9th. The lecturers will include Professor Malinowski, Dr. Crichton-Miller, and Dr. I. Feldman.—I am, etc.,

A. H. HARKNESS,
London, April 13th. Honorary Medical Secretary, British Social Hygiene Council.

Obituary

Dr. ARTHUR STANLEY, formerly commissioner of public health, Shanghai, died in London on March 28th, at the age of 62. He was educated at Truro, the Royal College of Science, South Kensington, Leeds University, and St. Mary's Hospital, London, where, after a distinguished career, he became assistant demonstrator of physiology. He graduated M.B.Lond. in 1894, and proceeded M.D. in the following year. After holding several appointments in England, including that of pathologist and assistant medical officer to the London County Asylum, Banstead, and assistant medical officer to the North-Western Fever Hospital, he was appointed in 1898 as the first full-time medical officer of health of the foreign settlement of Shanghai, and became its first commissioner of public health. He was a pioneer of public health in China, and his great gifts of organization and administration were devoted, often in the face of considerable difficulties, to establishing and developing the department, which has to-day a world-wide reputation, and is one of the most efficient and best-organized public health departments in the Far East. Among other divisions, he founded a Pasteur Institute, the first under British control, himself

acquiring the technique of antirabic treatment in Kitasato's laboratory in Tokyo, and undergoing a course of antirabic inoculation for prophylactic purposes. In 1911 he was a member of the commission appointed to investigate the epidemic of plague in Manchuria, and later his advice was sought and his services requested by the Chinese Government in the prevention of plague. His contributions to medical and other scientific journals were numerous and varied, and showed the wide scope of his scientific interest. Beyond his purely professional work, Dr. Stanley took a great delight in natural history, was a lover of literature and of music, and was an accomplished student of Chinese art. For many years he was curator of the museum of the North China branch of the Royal Asiatic Society, for which he prepared a comprehensive catalogue. He was at one time president of the society, and was a frequent contributor to its journal. His writings were lucid and graceful, and showed the delicacy and keenness of his aesthetic perception. He retired from Shanghai in 1921, and until the serious breakdown of his health a few months ago spent a happy life at Hampstead, with his family and among his friends, in a serene contemplation of nature.

The Rev. Canon ARNOTT, F.R.C.S., died at his residence in the Precincts, Rochester, in the last week of March, at the age of 88. He was the son of Dr. James Arnott, and began the study of medicine at University College. He took the diploma of M.R.C.S. in 1864, and was admitted to the Fellowship in 1868. He was elected to the staff of the Royal Northern Hospital, and was also assistant surgeon and lecturer on surgical pathology at the Middlesex and St. Thomas's Hospitals. Canon Arnott was always a deeply religious man, and in his student days, with three other students, he laid the foundations of the Guild of St. Luke, Evangelist and Physician, a society which is still flourishing and achieving excellent results. He was the last survivor of the original band of four, one of the others being the late Mr. Robert Brett, who practised in Stoke Newington, and whose memory still lives in that district. In 1876 Canon Arnott studied for the Church. He was rector of Beckenham for thirty-four years, and was later made an honorary canon of Rochester. He was laid to rest in Beckenham Churchyard on March 30th, after a service in Rochester Cathedral. It adds interest to the association of Canon Arnott with the medical profession that his wife, who predeceased him by a year, was a sister of the late Sir Richard Douglas Powell.

The following well-known foreign medical men have recently died: Dr. IGNAZIO SALVIOLI, for thirty-five years professor of general pathology at Padua, aged 68, of acute pneumonia; Dr. ROBERTO BINAGHI, professor of surgery and rector of the University of Cagliari, Sardinia; Professor FRIEDRICH KOVÁCS, director of the fourth medical department of the General Hospital, Vienna, aged 70; Professor BERNHARD VAS of Budapest, a distinguished histologist and chemist; Dr. WILHELM HERZOG, emeritus professor of surgical diseases of children at Munich; Dr. ALEXIS PISSAVY, physician to the Hôpital Cochin, Paris, aged 60; Dr. EDOUARD CADENAULE, a Bordeaux paediatrist, aged 75; Professor PAUL FÜRBRINGER of Berlin, an authority on genito-urinary diseases, aged 80; Professor CARL LEWIN of Berlin, author of several works on cancer, aged 54; Dr. AUGUST HOUBERGER, extraordinary professor of psychiatry and director of the psychiatric and neurological clinic at Heidelberg; Dr. LUIGI SALA, professor of normal human anatomy at Pavia, aged 67; Dr. RALPH WALDO WEBSTER, professor of clinical medicine at Rush College, Chicago; Professor ADOLPHE D'ESPINE, formerly occupant of the chair of children's diseases at Geneva, aged 85; Professor THEODOR AXENFELD, an eminent ophthalmologist of Freiburg, aged 63; Dr. JUAN ORRICO, professor of clinical paediatrics, Cordoba (Argentine Republic); and Dr. SIMOCS CORREA, formerly professor of children's diseases at Rio de Janeiro, aged 82.

Universities and Colleges

UNIVERSITY OF LONDON

Dr. R. A. Young has been appointed to represent the University at the annual conference of the National Association for the Prevention of Tuberculosis at Margate on June 25th to 27th, and Sir William Collins as the representative at the fourth centenary celebrations of the Collège de France, to be held in Paris from June 18th to 20th.

Presentation Day

The ceremony of presentation for degrees will take place in the Albert Hall on May 13th, at 2.30 p.m. The graduation dinner will be held in the evening at Drapers' Hall, under the presidency of the Chancellor of the University. The annual service for members will be held in Westminster Abbey on the same day, at 5.30 p.m.

Lectures

The Semon Lecture for 1931 will be given by Mr. W. D. Harmer, consulting surgeon to the throat department of St. Bartholomew's Hospital. The subject will be the relative value of radiotherapy in the treatment of cancers in the upper air passages.

A course of six lectures on medical aspects of dietetics will be given by Professor S. J. Cowell in the lecture room attached to the dietetic kitchen of St. Thomas's Hospital on May 7th, 14th, 21st, and 28th, and June 4th and 11th, at 5 p.m.

Two lectures on the treatment of malignant tumours by radium placed at a distance, with lantern illustrations, will be given by Dr. Max Cheval of Brussels at the Westminster Hospital Medical School on May 4th and 5th, at 5.30 p.m. Mr. E. Rock Carling will preside at the first lecture and Dr. H. T. Flint at the second lecture.

Professor Otfrid Förster, professor of neurology in the University of Breslau, will give three lectures on neurology, illustrated with lantern slides, at the University College Hospital Medical School, on April 29th and 30th, and May 1st, at 5.30 p.m. Mr. Wilfred Trotter will take the chair at the first lecture.

A course of three lectures on the pharmacology and therapeutics of lead colloids, with lantern illustrations, will be given by Professor W. J. Dilling of Liverpool University at King's College on May 7th, 8th, and 11th, at 5.30 p.m. Sir William Willcox will preside at the first lecture.

Mr. G. Grey Turner, professor of surgery in the University of Durham, will give two lectures on resection of the rectum, at St. Thomas's Hospital, on May 13th and 15th, at 5.30 p.m. The chair at the first lecture will be taken by Sir Percy Sargent.

Diploma in Public Health

It has been decided that the examination for the Diploma in Public Health shall be common for both internal and external students.

UNIVERSITY COLLEGE, LONDON

The annual dinner of the Fellows of University College, London, will be held at the College on Thursday, April 30th, at 7.15 for 7.30 p.m., that day being the anniversary of the laying of the first stone of the College buildings by H.R.H. the Duke of Sussex, on April 30th, 1827. Sir John Rose Bradford, M.D., F.R.S., will preside.

KING'S COLLEGE, LONDON

A course of three public lectures on the biophysical chemistry of colloids and protoplasm will be given by Victor Cofman, D.Sc., in the Biological Theatre of King's College, Strand, W.C.2, on May 4th, 11th, and 18th, at 5.30 p.m. Admission to the lectures is free without tickets; they will be illustrated by experiments and lantern slides.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

A quarterly council meeting of the Royal College of Surgeons of England was held on April 9th, when the President, Lord Moynihan, was in the chair.

Diplomas

The Diploma of Fellowship was granted to K. H. Pridie.

The following Members of twenty years' standing were elected to the Fellowship: George Henry Edington, M.D., D.Sc.Glas., and Ernest Frederic Neve, M.D., F.R.C.S.Ed.

Diplomas of Membership were granted to Inez E. Banner, W. Dodd, and Margaret M. White, who had complied with the by-laws.

The Licence in Dental Surgery was granted to M. A. B. Brito-Mutunayagam.

Diplomas in Tropical Medicine and Hygiene were granted jointly with the Royal College of Physicians to thirty candidates. (The names were printed in the report of the meeting of the Royal College of Physicians of London, published in the *Journal* of April 11th, p. 651.)

Prizes

The Jacksonian Prize for 1930 was awarded to E. S. J. King, F.R.C.S. (Melbourne), for his dissertation on "The pathology of ovarian cysts and its bearing on their treatment." A certificate of honourable mention was awarded to Wilfred Shaw, F.R.C.S. (St. Bartholomew's Hospital). It was decided that the subject for the Jacksonian Prize for 1932 should be "The pathology, diagnosis, and treatment of diverticuli of the large and small intestine."

The John Hunter medal in bronze with the triennial prize of £50 was awarded to Thomas Bramley Layton, D.S.O., M.S., F.R.C.S., for his contributions to otology, and for his valuable services to the museum, particularly in connexion with the Onodi Collection.

The Walker Prize of £100 was awarded to Sir G. Lenthal Cheatle, K.C.B., C.V.O., F.R.C.S.

The committee appointed by the council for the administration of the Walker Prize Fund reported as follows: "The work of Sir Lenthal Cheatle, continued over many years and up to the present time, has been of great help to surgeons in the elucidation and treatment of the precursory conditions of cancer of the breast. It has shown that cancer is preceded by papillomatous hypertrophies chiefly affecting the smaller ducts of particular lobes of the breast, and often associated with the formation of cysts due to distension of the duct system. The methods employed have been laborious and systematic, and have correlated the microscopic and macroscopic anatomy of the conditions studied. This has involved the making of whole sections of the breast by means of the giant microtome, an instrument of which this work has shown the great value. The committee considers that Sir Lenthal Cheatle has thus made a definite and important contribution towards the solution of the etiological problem of cancer of the breast."

The Cartwright Prize for 1926–30 was awarded to F. W. Broderick, M.R.C.S., L.D.S. (Bournemouth), for his essay on "The etiology, pathology, and treatment of chronic general periodontitis (pyorrhoea alveolaris)." The subject for the Cartwright Prize for 1931–35 is "The relationship of pulpless teeth to general disease and their treatment, with special reference to periapical rarefaction."

Appointment of Representatives

Lord Moynihan was appointed to represent the College on the Governing Body of the proposed British Post-Graduate Hospital and Medical School. A petition for a Royal Charter of Incorporation will shortly be presented. Lord Moynihan was appointed to represent the College at the celebration, at the end of September, of the fiftieth anniversary of the opening of the Natural History Museum building at South Kensington.

Lectures

Colonel Robert McCarrison, C.I.E., I.M.S., was appointed to give two lectures at the College.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND

The following were elected Fellows of the College on April 10th: John George Cullinane, Robert Allen Quain O'Meara, and Vishwa Nath.

The Services

ROYAL AIR FORCE MEDICAL SERVICE

In the *Journal* of April 4th (p. 608) the report of a parliamentary discussion on the shortage of medical officers in the Royal Air Force contained a statement that the "deficiency was in large part made up by the employment of short-service officers on a commissioned or a civilian basis." It has been pointed out to us that the word "contract" should be read instead of "short-service." The regular medical officers in the Royal Air Force comprise those holding either short-service or permanent commissions. All enter on short-service commissions for three years (sometimes extendable to five), and a certain number are selected and appointed to permanent commissions during these years. The deficiency in numbers of these officers is partly made good by employing doctors either as commissioned officers on a yearly contract or as civilians on a short contract terminable by either side at a week's notice.

DEATHS IN THE SERVICES

Major-General Sir Tom Percy Woodhouse, K.C.M.G., C.B., late R.A.M.C., died at the house of his son-in-law, Lord Kingsale, at Coffinswell, Devon, on April 10th, aged 73. He was born at Pontefract on August 10th, 1857, the son of Mr. John Woodhouse of Marlpit House, Pontefract, was educated at St. Paul's College, Stony Stratford, and at St. Thomas's, and took the L.S.A. in 1879 and the M.R.C.S. in 1880. Entering the Army as surgeon on February 5th, 1881, he became lieutenant-colonel after twenty years' service, brevet-colonel on April 8th, 1909, colonel on November 17th, 1909, and surgeon general on July 14th, 1914. He was retained on the active list for some months after attaining the age of 60, and retired on December 26th, 1917, his title of rank being changed to major-general in 1918. He served throughout the South African war (1899–1902), taking part in the operations in Cape Colony, the Orange River Colony, and the Transvaal, including the relief of Ladysmith, was mentioned in dispatches in the *London Gazette* of February 8th, 1901, and received the Queen's medal with three clasps, and the King's medal with two clasps. From 1909 to 1913 he was P.M.O. of the Scottish Command, and became D.D.M.S. of the Aldershot Command in 1914. During the war of 1914–18 he served as Director of Medical Services in France, was mentioned in dispatches in the *London Gazette* of October 19th, 1914, January 1st, 1916, and May 29th, 1917, was made C.B. in 1915, and K.C.M.G. in 1917, and also Commander of the Legion of Honour, and Commander of the Order of the Crown of Belgium in 1917. After the war he filled the post of Deputy-Inspector of Medical Services in the War Office in 1918–19. In 1881 he married Mary Hannah, daughter of Mr. John Holmes Greaves of Carleton Hall, and leaves a son, Lieut.-Colonel Percy St. John Rance Woodhouse, O.B.E., late Indian Army, and two daughters, the elder of whom is Lady Kingsale, while the younger is the wife of Flying Officer E. N. Hewitt, R.A.F.

Lieutenant Desmond Blewitt, R.A.M.C., died in Cairo on February 22nd. He was educated at Trinity College, Dublin, where he graduated as M.B., B.Ch., and B.A.O. in 1927, and joined the R.A.M.C. as lieutenant on December 13th of that year.

BRITISH EMPIRE CANCER CAMPAIGN

The quarterly meeting of the Grand Council of the British Empire Cancer Campaign was held on April 13th, with Sir JOHN BLAND-SUTTON, Bt., in the chair.

The finance report showed that, including grants approved at the meeting, the Campaign had now subsidized research centres and independent research workers since its inception to the extent of £157,000. Apart from this, over £500,000 had been subscribed and is being administered by the branches and affiliated organizations of the Campaign throughout the British Empire.

On the recommendations of the executive committee, the council approved the following grants: £2,500 to the Cancer Hospital, London, for its general research work, together with £500 to meet the expense incurred by the Research Institute by the appointment of its biochemist, Dr. J. W. Cook; £650 for one year to St. Mark's Hospital, City Road, and £2,500 to St. Bartholomew's Hospital. For the sixth year in succession the council renewed the grant of £680 to the Medical Research Council towards the upkeep of the Radon Centre at the Middlesex Hospital, which supplies a number of organizations with radon for scientific experimental investigations.

Mr. S. A. Courtauld and Mr. R. H. Jocelyn Swan, F.R.C.S., were elected members of the council as the representatives respectively of the Middlesex Hospital and the Cancer Hospital. Professor W. S. Lazarus-Barlow, M.D., was elected to fill the vacancy in the five nominees of the Campaign on the Scientific Advisory Committee, the other five members of which are nominated jointly by the Royal Society and the Medical Research Council.

The council acceded to the request that the Glasgow Royal Cancer Hospital should be affiliated officially to the British Empire Cancer Campaign. Although a considerable amount of cancer research work has been carried out hitherto, aided by funds from the Campaign, in Scotland, this is the first organization in Scotland to become affiliated to it.

It was arranged that the annual general meeting of the Campaign should be held on Monday, July 20th, and it was reported that the President, H.R.H. the Duke of York, had intimated his intention of being present.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

MINISTRY OF HEALTH VOTE

Mr. Greenwood's Speech

When the House of Commons reassembled on April 14th, the Minister of Health (Mr. GREENWOOD) moved a vote of £19,616,212 for the salaries and expenses of the Ministry.

National Health Insurance

Mr. Greenwood said that national health insurance had given a good deal of trouble. The House was well aware of the increased expenditure of approved societies in recent years on sickness and disablement benefit. About a year ago the report of the Government Actuary drew attention to these very disturbing facts. Since then a special Interdepartmental Committee had been investigating this trouble further. It was very difficult to assess the exact weight which should be given to the various factors causing this increase of expenditure. He was not satisfied that there had been any substantial deterioration in the general health; there might have been here and there, and in particular areas. It was largely due to the fact that there had been an expansion of additional benefit using up reserves created in earlier years, and partly because insured persons were properly taking full advantage of the rights which the law had conferred on them. It was very important that in the early stages of illness the insured person should go to the doctor and get the earliest possible treatment. But, behind all legitimate causes, everyone associated with approved society work knew that there was undoubtedly a certain amount of laxity. There could be no desire on the part of any member to deprive any sick person of what was due to him. On the other hand, there would be no difference of opinion as to the desirability of depriving people of benefit to which they were not entitled. The Ministry of Health was issuing to all approved societies memoranda which, he hoped, would be of assistance in the matter of certification and supervision of claims for benefit. Last year the amount paid out in sickness benefit was £2,000,000 less than in the previous year. That was due to the fact that 1930, on the whole, was a pretty good year compared with 1929 in regard to sickness, and also partly, no doubt, to the fact that there had been some improvement in administration. The great increase in the expenditure of societies in sickness and disablement benefit was naturally reflected in the financial condition of the approved societies. They had now almost completed the third valuation of the approved societies. It would be found that the big majority of societies would still have disposable surpluses out of which they would be able to continue to pay additional benefits during the next five years. There were societies, however—and especially those which had separate funds for women, where the drain had been more than the average—whose disposable surpluses, unfortunately, had fallen to very small dimensions, or had entirely disappeared. That was a serious problem which was now under sympathetic consideration.

Maternal Mortality

There could be no difference of opinion as to the seriousness of the problem of maternal mortality. They could not attempt to justify the death of 3,000 mothers a year in the existing state of knowledge. It made maternity the most dangerous occupation of this country, and the Departmental Committee on Maternal Mortality appointed by Mr. Chamberlain three years ago had examined these deaths, and had arrived at conclusions which were serious. He could say, on the basis of the finding of this committee, that not less than one-half of these maternal deaths were preventable. That was a national scandal. After consideration of the report he had approached the local authorities in a circular, pointing out to them ways in which they might co-operate in this problem. At the end of March he had received replies from seventy local authorities. Of these, thirty-six had adopted proposals for improving their maternity services, while a number of others had these matters still under their consideration. Fifteen authorities were establishing or extending their ante-natal clinics, ten were providing private medical practitioners for ante-natal examinations; twelve were improving their arrangements for the supply of midwives; twenty-one were arranging consultant services; nine were providing or extending hospital accommodation; and a number of others were arranging various ancillary services. Thus, in the three months since the circular went out, there had been an earnest intention on the part of the local authorities to co-operate with the Ministry in an attack on this problem. He was keeping in touch with the local authorities to see that, so far as possible, they acted up to their responsibilities. Any national scheme would involve the services of those authorities. The figures of maternal mortality for the past year were about the same as for the year before.

Post Graduate Medical Education

As to the Post Graduate Hospital and Medical School, his predecessor had presided over a committee, and it had been his privilege to complete that work. He believed that the Post-Graduate Hospital and Medical School was perhaps the biggest single step taken in this country in the interests of public health since the war, and he made no party capital out of it at all. When the report of the committee came to hand, he asked Lord Chelmsford to be the chairman of an organization committee to work out the details. This had been done, and they were now beginning the task of setting up the governing body of this institution. The Government was prepared to provide up to £250,000 for the actual building of the medical school, and would continue to make grants to the school. He believed that in the very near future the school and hospital would be actually at work, and would exercise a very profound influence on the public health of the country.

Local Government Act, 1929

They could congratulate themselves on the smoothness with which the transfer of functions under the Local Government Act, 1929, had taken place. One of the purposes of the Act was to promote the break-up of the old Poor Law system. On the whole, having regard to the fact that only one year had elapsed, a good deal had been done in the direction of the break-up of the Poor Law. Sixteen county councils and forty-nine county borough councils had found it possible to make immediate declarations in their schemes. These consisted of twenty-four by county borough councils under the Public Health Acts, one by a county council, and sixteen by county borough councils under the Mental Deficiency Acts; three by county councils and thirty by county borough councils under the Maternity and Child Welfare Act; ten by county councils and thirty-three by county borough councils under the Blind Persons Act; three by county councils and sixteen by county borough councils under the Public Health (Tuberculosis) Act; and nine by county councils and forty-one by county borough councils under the Education Act. Twenty county borough councils had appropriated their Poor Law institutions to Public Health Act purposes; three county borough councils had appropriated Poor Law institutions for Maternity and Child Welfare Act purposes; and four county councils and one county borough council had appropriated their Poor Law institutions for purposes of the Mental Deficiency Act. The London County Council had appropriated twenty-seven Poor Law institutions for the purposes of general hospitals, and ten for the purpose of children's hospitals or convalescent homes.

Housing Act, 1930

Since the war very little had been done in the way of slum clearances. He believed that local authorities were fully alive to the responsibility for slum clearances placed on them by the Act last year. He was, however, bound to point out that if there should be local authorities which failed to realize their responsibility in that respect, the powers entrusted to the Ministry by the Act would be exercised. Such authorities as failed to realize their responsibility must expect that the rigours of the law would be used against them.

Dr. FREMANTLE asked for an assurance that the authoritative report on the question of tuberculous cattle, which was presented three months ago, would be published without delay. He said that the restriction on the change of doctor in connexion with the insurance regulations was considered by the medical profession to be a most retrograde step. There ought to be greater co-operation between the Ministry and the local authorities in the appointment of medical officers of health.

Dr. MORRIS-JONES said that he was very glad to hear what Mr. Greenwood had said about the post-graduate course. The general practitioners were the first line of defence against illness, and he hoped that the Government would give facilities to them to come to London from time to time to review their knowledge. He was, however, very disappointed with the general review given by the Minister of Health.

Mr. LEWIS moved a reduction of the vote by £100.

Dr. ELLIOT said that the vital question of public health, and of whether the physical condition of the nation was becoming rotten or improving, merited a whole day's discussion. It was more than ever necessary to examine this question at present, to see whether the long-continued stress of unemployment was being reflected in the physical condition of the nation.

Miss LAWRENCE replied for the Government, and the motion to reduce the vote was defeated.

Medical News

On Monday, April 20th, at 8.15 p.m., Sir Arthur Keith will deliver an address entitled, "Fresh Light on John Abernethy," before the Abernethian Society at St. Bartholomew's Hospital.

At a meeting of the Royal Society of Arts at John Street, Adelphi, W.C., on Wednesday, April 22nd, at 8 p.m., Professor Major Greenwood, F.R.S., will read a paper on the work of the London School of Hygiene and Tropical Medicine. The paper will be followed by a demonstration of a malaria film by Professor J. Gordon Thomson. Dr. Henry S. Wellcome will preside.

At a meeting of the Royal Sanitary Institute to be held in the Town Hall, Batley, on Friday, May 1st, at 5 p.m., under the chairmanship of Professor W. W. Jameson, M.D., papers will be read on housing, with special reference to the Housing Act, 1930. On the following morning there will be a discussion on the practical value of meat inspection.

The annual meeting and luncheon of the Tavistock Square Clinic for Functional Nervous Disorders will be held at the Wharncliffe Rooms, Hotel Great Central, on Monday, May 11th, under the chairmanship of Dr. H. B. Brackenbury.

A meeting of the Medico-Legal Society will be held at 11, Chandos Street, W.1, on Thursday, April 23rd, at 8.30 p.m. Dr. Percy B. Spurgin will read a paper on "The Harley Street Mystery," which will be followed by a discussion.

At a meeting of the London Society to be held to-day (Friday, April 17th), at 5 p.m., in the Hall of the Royal Society of Arts, 18, John Street, Adelphi, W.C., Dr. Dan McKenzie will read a paper on "Noise: A modern plague of London."

Several special courses have been arranged by the Fellowship of Medicine to be held before Whitsun, and there is also a series of seventeen lectures for the M.R.C.P. examination, on Tuesdays and Fridays, at 8.30 p.m., in the House of the Medical Society of London. Copies of syllabuses and tickets of admission can be obtained from the Fellowship, 1, Wimpole Street, W.1.

A post-graduate course in diseases of the nervous system will be held at the National Hospital, Queen Square, from May 4th to June 26th. The general course will consist of thirty-two lectures and demonstrations at 3.30 p.m. chiefly on methods of examination of the nervous system, each week-day except Wednesday and Saturday; teaching in the out-patient department, and pathological lectures and demonstrations. The fee for the course is £6 6s. A course of ten lectures on the anatomy and physiology of the nervous system will be arranged on Wednesdays and Fridays at 12 noon if there are sufficient applicants; fee £2 2s. A course of twelve clinical demonstrations will be given on Tuesdays and Thursdays at 5 p.m.; fee £2 2s. Applications should be addressed to the secretary, Medical School, National Hospital, Queen Square, W.C.1.

A series of free public lectures will be given in the Public Health Division of the London School of Hygiene during the forthcoming summer term. The course opens with four lectures on the laws of inheritance, by Professor F. A. E. Crew, on April 28th, 29th, and 30th, and May 1st, at 5 p.m. Subsequent lecturers include Dr. C. F. White, Dr. J. J. Buchan, Dr. Bernard Hart, Professor E. L. Collis, Dr. R. H. Crowley, Dr. F. C. Shrubsall, Dr. Howard Mummery, Dr. C. J. Thomas, Sir George Buchanan, and Sir Thomas Legge. An important series of lectures—the first under the terms of the Heath Clark Bequest to the University of London—is announced to be given in the school on May 4th, 5th, 6th, 7th, and 8th, at 5 p.m., by Sir George Newman, who has taken as his subject "The rise of preventive medicine." The chair at the lecture on May 4th will be taken by the Right Hon. Arthur Greenwood, M.P., Minister of Health. A list of all these lectures can be obtained on application to the secretary, London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C.1.

A post-graduate course in cardiology will be held at the Liverpool and District Hospital for Diseases of the Heart from May 4th to 15th inclusive. The course is limited to twenty, and the fee is £1 1s.

The midwifery centre of the Nursing Sisters of St. John the Divine, at St. John's Home, Watson Street, Deptford, will be opened on Wednesday, April 29th, at 3 p.m., by Dame Janet Campbell, M.D. The chair will be taken by the Bishop of Woolwich.

The sixth International Congress of Military Medicine and Pharmacy will be held at The Hague from June 15th to 20th. The subjects to be discussed include the recruiting, organization, and training of military medical officers; the immediate and remote effects of war neuroses; the methods of arresting haemorrhage in the field; and the sequels of injuries to the jaws and teeth. Special arrangements for the journey to The Hague and back are in the hands of Thomas Cook and Son, Berkeley Street, W.1, to whom inquiries should be addressed. The general secretary of the congress is Jhr. R. Sandberg Van Boelens, 3, Surinamestraat, The Hague, from whom further details may be obtained. The fee for those attending as delegates is 10 Dutch florins, and for their friends 5 florins; special travel reductions are obtainable.

According to an estimate given by the *Journal of the American Medical Association* for March 28th, approximately two-thirds of the active medical practitioners of the United States are now connected with hospitals. In 1929 there were 152,503 licensed physicians, about 10,000 of whom were not in practice. Of the 142,500 who were in practice, 98,491 were connected with hospitals as staff members, superintendents, residents, and interns. In 1929 the numbers of practitioners in the various specialties were: internists, 3,378; surgeons, 12,939; neuropsychiatrists, 1,973; radiologists, 1,653; dermatologists, 896; pathologists, 672; paediatricians, 3,505; obstetricians and gynaecologists, 6,108; orthopaedists, 810; ophthalmologists, 1,343; oto-rhino-laryngologists, 6,805; specialists in tuberculosis, 984; urologists, 2,249; other specialists, 1,972.

The first annual report of the Institute of Ray Therapy in the Camden Road, London, N.W., contains encouraging news of the activities of the institute since its formal inauguration in March, 1930. During the year 1,450 patients were under treatment, having been referred to the clinic by general practitioners. The chief diseases treated were various rheumatic conditions, general debility, asthma, bronchitis, nervous conditions, skin diseases, and children's ailments; and out of 500 patients discharged, 400 were fit for work. The clinic is under the charge of an honorary medical director, and there is a training course for qualified nurses in matters relating to ray therapy.

Dr. R. Prosser White has been elected an honorary member, and Dr. H. W. Barber and Dr. A M H Gray corresponding members, of the Vienna Dermatological Society.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM* 9561, 9562, 9563, and 9564 (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Medusera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish *Office*, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS

Wagstaff's Forceps

"CROYDONIAN" writes: Would any reader of the *British Medical Journal* give his experiences of Wagstaff's obstetrical forceps? They are praised by Stark in his work on general practice, but I can find no reference elsewhere. How does one distinguish upper from lower blade, and how does one determine the correct axis of pull?

Hemicrania

Dr. R. A. HOLLINGSWORTH (Sydenham) asks for suggestions in the treatment of the following case. A lady, aged 50, has suffered from migrainous attacks from the age of 15. The attacks have always been of the severest type, the pain being above concert pitch. Of late they have become more frequent, barely a week elapsing between them. The pain is worse when it settles in the left eyeball, and is attended with severe vomiting. The intensity of the pain is such that the patient asserts that she is hardly able to see with the left eye at the height of the paroxysm. An attack usually lasts three to four days, during which no food can be retained. There is evidence of hypopituitarism. The eyes have been examined, and suitable glasses prescribed. The teeth are in good condition. The bowels are constipated, and are only opened by laxatives. The liver is peculiarly intolerant to such drugs as calomel and ammonium chloride, a dose of any of these precipitating a typical attack of biliary colic. Eight years ago the patient was operated on for gall-stones. All the usual drugs, such as bromides, phenacetin, antipyrin, and aspirin, have been tried to little or no purpose. Morphine injections alone afford relief from pain, but the undesirable after-effects of this drug, coupled with the nerve-exhausting nature of the attacks themselves, are seriously undermining the patient's general health.

Coincident Zoster and Varicella

Dr. J. BORRIE HARRIS (Armagh) writes, in reply to Dr. S. R. Hunter (April 4th, p. 610): The herpes zoster is very likely the cause of the varicella. Sir James Purves-Stewart, in his *Diagnosis of Nervous Diseases*, states: "The infective organism which produces herpes is apparently identical, in many cases, with that of varicella, for a chicken-pox epidemic may take its starting-point from a case of herpes zoster" (vide also Bokay, *Wien. klin. Woch.*, September 30th, 1909, and R. C. Low, *British Medical Journal*, January 25th, 1919). Osler also points out that varicella may then attack adults who have escaped in childhood, and he, too, refers to the association with herpes zoster. Some time ago, when in Scotland, I treated a male patient, aged 38, who developed varicella while suffering from herpes zoster, although there was no other case of varicella in the neighbourhood. On another occasion, in a small town similarly free from varicella, a child developed varicella while living in the house of a patient who had herpes zoster.

Income Tax

Change in Share of Partnership Profits

"R. O. E." was a partner on the basis of one-third share to January 1st, 1931, and subsequently on a one-half basis. How will his liability be calculated for 1931-32?

*** On one-half of the amount of the profits of the year 1930. Further, his proportion of the gross assessment for the year ended April 5th, 1931, should be three-quarters of one-third + one-quarter of one-half = one-quarter + one-eighth—that is, three-eighths.

Earnings Abroad during Short Period

"MAHARAJAH" left England on March 14th, 1930, to take up an appointment in an Indian Native State which was expected to last some years. Owing to unexpected circumstances the appointment was of short duration, and our correspondent arrived back in England on September 5th, 1930. Is he liable to income tax here on the earnings of the appointment? No residence was maintained in the United Kingdom during his absence. The remuneration was paid in India in rupees.

*** The circumstances are unusual, and in our opinion "Maharajah" is not liable in respect of the earnings accruing to him while abroad. If in the absence of due notice he received as pay, or in lieu of pay, sums calculated to cover a period ending after September 5th, 1930, then he would apparently be liable in respect of pay accruing for a period after that date.

LETTERS, NOTES, ETC.

Visit of Scientists to Russia

We have received the following letter for publication from Lady Sprigge (chairman), Sir Peter Chalmers Mitchell, and Professor Julian Huxley, on behalf of the Society for Cultural Relations between the Peoples of the British Commonwealth and the U.S.S.R.: It is proposed to organize a tour of scientists to the U.S.S.R., and the first party will leave London Bridge by Soviet ship for Leningrad on July 18th. The return fare will be £18 inclusive. The party will spend a total of sixteen days in Russia: three days in Leningrad, five days in Moscow, half day in Nizhni-Novgorod, and four days on the river down to Stalingrad (if desired), and the cost per day will be £1 per head inclusive, the balance of the days being spent in travelling. Meetings will be arranged, which members of the party will be invited to address, and there will be excursions, with guides, to scientific institutions of interest to the members. The Soviet authorities are prepared to give this tour second category accommodation at third category prices. The accommodation will be comfortable, and persons will sleep three or four in a room. Those wishing to sleep two in a room will pay 5s. per day extra. In the first instance, the party will consist of twenty-five persons. If there is a large demand for places a second party will be made up of twenty-five; the Russian authorities are prepared to accommodate up to one hundred persons if necessary. A further party may be arranged, if sufficient names are received, to leave London about the second week of August, returning to London in time for the British Association Meeting. The latest date for receiving applications is April 30th. Applications and all inquiries should be addressed to the secretary, Society for Cultural Relations, 1, Montague Street, W.C.1.

Filter-tipped Cigarettes

A device for intercepting the acrid constituents of tobacco smoke without impairing its flavour or obstructing free draught has been introduced by the firm of Peter Jackson (Tobacco Manufacturers) Ltd., in their du Maurier Virginia filter-tipped cigarettes. The cork-covered tip is made up of three layers of crinkled vegetable tissue, interleaved with two layers of absorbent cellulose, the edges of the coiled layers being presented axially. The aim of this ingenious filter is to trap the irritating pyridine derivatives and other non-volatile bodies, while permitting free passage of the agreeable volatile constituents of tobacco smoke.

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 55, 56, 57, 58, 59, 62, and 63 of our advertisement columns, and advertisements as to partnerships, assistantships and locumtenencies at pages 60 and 61.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 127.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

366 Etiology of Sero-fibrinous Pleurisy

In an endeavour to elucidate the etiology of primary serous pleurisy and to determine if a differential diagnosis can be made between undoubtedly tuberculous exudations and those of uncertain origin, A. LANDAU, J. GLASS, and M. MARKSON (*Ann. de Méd.*, January, 1931, p. 41) have recorded a careful study of 28 cases. Their investigations indicated that the two types were almost indistinguishable, such differences as existed being too slight to be of diagnostic value. In 54 per cent. of the cases the origin was proved to be tuberculous; in 46 per cent. the etiology was uncertain, but in 27 per cent. of these a tuberculous etiology was strongly suspected. The authors agree with the French school that all primary pleurisies are tuberculous. The negative results of guinea-pig inoculations in some cases may be due to bacteriolytic properties of the exudate, or to the occurrence in them probably of an attenuated type of the Koch bacillus. In the cases of secondary pleurisies, of which only 50 per cent. were tuberculous, other etiological factors, such as streptococci and pneumococci and influenza bacilli, were present. The absence of a tuberculous causation in cases of secondary pleurisy must be proved by the negative results of animal inoculations, by the existence of a plain and direct relation between the effusion and another focus of infection such as rheumatism or influenza, and by the eventual discovery of the causal micro-organism.

367 Cerebral Aspergillosis

E. MONIZ and R. LOFF (*Presse Méd.*, February 21st, 1931, p. 273) record a case of cerebral aspergillosis in a woman, aged 44. Three years previously the patient had suffered from an inflammation of the left eye, with great pain in the globe and immediate amaurosis of that eye. When admitted to hospital a grave iridocyclitis was present, associated with mental disturbances and great intellectual torpor. Headache and vomiting were absent. Examination showed a right hemiplegia with involvement of the lower facial nerve branches and slightly of the upper ones. No cerebellar troubles were apparent. A diagnosis of syphilis was entertained, but specific treatment produced no improvement. Death occurred in four days; the necropsy revealed an extensive aspergillosis in the left frontal region, which extended to the centrum ovale and posteriorly into the caudate nucleus and internal capsule. Mycotic infections of the eye have been reported, but the condition is usually limited to the external ocular media. In the present case the fungus had evidently reached the brain through a corneal ulceration. The authors emphasize the possibility of such transmission and the need of immediate appropriate treatment when a diagnosis of ocular aspergillosis is made. They also note the slow evolution of the cerebral condition.

368 Fourth Disease

DRENKHAHN (*Deut. med. Woch.*, February 20th, 1931, p. 319), who records an illustrative case, states that in 1917 an epidemic occurred among the children in Godesberg which was regarded as "fourth disease." On this occasion his patient, a girl aged 8 years, contracted the disease, as did four other members of the family. Thirteen years later, when she was employed as a hospital nurse in charge of infants within the first eight months of life who were not suffering from any infectious disease, she developed similar symptoms—namely, a scarlatiniform rash, with a negative extinction sign, fever, and sore throat. There was no desquamation. She was sent home, where twelve days after the onset of the disease two children showed similar symptoms, except that there was also a branny desquamation. In none of the cases was there any renal involvement.

369 Insulin Oedema

I. H. MARCUS (*Med. Journ. and Record*, January 7th, 1931, p. 12) reports a case of the occurrence of oedema during insulin therapy, in view of the rarity of references in the literature to this complication. In a married woman, aged 32, oedema appeared in the legs on the fifth day after starting insulin injections for diabetes, and spread thence to the thighs; the eyelids were also affected. The patient gained 19 lb. in weight in less than a fortnight. Her fluid intake had been excessive, though this was not the case as regards mineral salts. Recovery ensued without any restriction of salts being found necessary. Marcus discusses the various etiological explanations which have been put forward, and concludes that the mechanism of its production is unknown. Retention of water by the body during the first days of a course of insulin therapy seems to be frequent, possibly owing to some increase of the hydration capacity of the tissue colloids.

370 Meningococcaemia with Endocarditis

A. M. MASTER (*Journ. Amer. Med. Assoc.*, January 17th, 1931, p. 164), who records three illustrative cases in a man aged 30, a boy aged 11, and a woman aged 48 respectively, states that though the number of cases of meningococcaemia on record is increasing, the disease is still relatively rare. Its similarity to subacute bacterial endocarditis is shown in the embolic phenomena in the skin, kidneys, and spleen, the fungating endocarditis often engrafted on an old rheumatic endocarditis, the septic course, the joint pains without local inflammation, and the positive blood cultures. Although many writers regard endocarditis as a rare complication of meningococcaemia, endocarditis may be present without any clinical evidence, as is shown by Mackarell's case, in which a massive fungating mitral endocarditis was found at the necropsy. All Master's patients recovered, the diagnosis of endocarditis being made by clinical examination and the teleroentgenogram and electrocardiogram.

Surgery

371 Diverticula of the Urinary Bladder

W. E. LOWER (*Surg., Gynecol. and Obstet.*, February 15th, 1931, p. 324), from a series of 151 cases, points out that diverticula of the urinary bladder may exist without causing any symptoms suggestive of their presence. Their most usual site is in the lateral wall near the ureters. They may be single or multiple, arising from some congenital defect which becomes intensified by obstruction to the urinary outlet. While they may occur at any age, over 80 per cent. were detected only after the age of 50. Frequency and difficulty in urination, with a pyuria persisting after repeated irrigations, should lead to this condition being suspected, but the best diagnostic method is by radiographic examination of the bladder from different angles after catheterization, and refilling with a solution of sodium iodide. Apart from prostatic conditions, the commonest complications are vesical infection, calculi, and tumours. It is generally agreed that complete excision is the only satisfactory treatment. To avoid recurrence any obstruction likely to have been a causative factor should also be removed. Under spinal anaesthesia the bladder is explored through a suprapubic incision; the diverticula are located, and the mode of procedure is determined. By converting the collapsed diverticulum into a semi-solid mass by packing it with gauze tape from within the bladder it can be approached from outsid the bladder, and its attachment be severed and the bladd opening closed. When the ureter is involved it may necessary to transplant it, retaining its physiologi function as far as possible. The prognosis is good if

radical operation is performed early, and before the renal impairment has become marked. Such an operation is the method of choice because it affords greater relief than can be obtained by palliative measures.

372 Minimal Exploratory Laparotomy

J. SOUZA MENDES (*Rev. Sud-Amér. de Méd. et de Chir.*, January, 1931, p. 45) advocates a method consisting in a direct inspection of the peritoneal cavity through an incision not more than 2 cm. in length, with the aid of a Killian's nasal speculum and a head-lamp. A long pair of Hartmann's forceps is employed to push aside coils of intestine which impede a view of the region inspected. It is claimed that this procedure can be conducted with the aid of novocain anaesthesia alone. The method is recommended in particular for the following conditions: (1) in cases of abdominal contusion where rupture of gut is suspected; (2) in perforating wounds of the abdominal wall, the wound itself providing an opening for inspection; (3) where it is desirable to make a certain decision about the site and extent of tumours before a major operation, and sometimes for the removal of biopsy specimens, or of fluid from cystic tumours, when transabdominal puncture is difficult or dangerous; (4) in cases of chronic peritonitis, to facilitate direct inspection of characteristic tuberculous or neoplastic lesions; and (5) in certain cases where direct inspection of the stomach, duodenum, or gall-bladder is a valuable preliminary to ordinary laparotomy.

373 Pseudarthroses of the Neck of the Femur

J. LEVEUF (*Presse Méd.*, February 11th, 1931, p. 204) refers to Delbet's work during the last twenty years on fractures of the neck of the femur; transcervical fractures, unlike the cervico-trochanteric variety, seldom unite spontaneously, and it is with the first of these that the present article is concerned. In a recent thesis the percentage of good results under present-day treatment was given as 37.5 per cent., a figure which contrasts unfavourably with the 95 per cent. of Leveuf, who judges by the functional result in reference to walking. Inquiring into the cause of this discrepancy, he emphasizes the importance of realizing that in transcervical fractures there is always some destruction of the remains of the femoral neck. So long as there is apposition between the trochanter with the remains of the neck and the head, correct anatomical realignment of the parts is not essential for a good functional result; a simple pegging operation with a fibular graft as practised by Delbet ensures good bony union, the graft acting simply as an osteogenetic factor. In recent years surgeons have attempted to overcorrect the displacement by extension; as a result the graft has had considerable strain imposed on it, and has consequently failed to induce union in a large percentage of cases. Leveuf holds that the original technique of Delbet (which does not involve arthrotomy) gives much the best prospect of good functional result, and that the more severe operations of arthrotomy and ablation of the head of the femur are not justified as procedures of election.

374 Staphylococcal Septicaemia

B. COHN (*Med. Klinik*, February 13th, 1931, p. 243), who records an illustrative case, states that septicaemia due to haemolytic staphylococci is a relatively rare but prognostically very unfavourable disease; only one of 24 patients treated by Jochmann recovered. Almost nine-tenths of Lenhartz's cases were fatal, and of Soper's 40 patients 29 died. Otten lost 44 of his 55 cases, a mortality of 80 per cent. The staphylococcal differs from other forms of septicaemia by its well-marked tendency to the formation of metastases, especially in the cases of boils of the lip, also by giving rise to paranephritic abscesses, pulmonary abscesses, and occasionally pulmonary gangrene. Cohn's patient was a man, aged 24, who developed staphylococcal septicaemia secondary to a boil on the upper lip. Little effect resulted from the injection of antistaphylococcal serum, and empyema followed by septic myocarditis ensued. Gradual improvement, however, took place, and finally the patient completely recovered.

Therapeutics

375 Strychnine in Alcoholic Delirium

P. PAGNIEZ and P. CHATON (*Presse Méd.*, February 28th, 1931, p. 297) believe that strychnine as a remedy for alcoholic delirium has undeservedly fallen into disuse. This method of treatment was introduced by Luton over fifty years ago, and although it is still sometimes used in delirium tremens, its value in alcoholism in general has been largely neglected. The authors believe that strychnine is valuable at all stages of the malady, and their procedure is to inject its sulphate in doses of 2 mg. every three hours, or in severe cases every two hours; amounts of 10 to 16 mg. are thus given every 24 hours. Small frequent doses are indicated, since the drug is eliminated rapidly from the body. Fluids are given freely. If restlessness is not excessive the patient is left at liberty in his room, which contains only a mattress. When there is great violence, or a medical or surgical complication such as pneumonia, the patient is restrained, and no ill effects have resulted from tying him to the bed. Confusion, hallucinations, tremulousness, and sweating are all generally relieved within twenty-four or forty-eight hours; when this stage is reached the amount of strychnine is reduced to 10 and 8 mg. daily, and is gradually further diminished. No dangers have been encountered in this treatment, and good results have been obtained in 42 serious cases, some being complicated by fever, pneumonia, or fracture. No such beneficial effect is obtained in non-alcoholic delirium, nor has the drug any harmful effect in these patients. The specific value of strychnine in alcoholism is attributed by the authors to a pharmacological antagonism, and they quote the work of Vulpian, who showed that dogs to which alcohol had been administered were protected from the harmful effect of normally lethal doses of strychnine given by the mouth.

376 Mercurialism following the Application of Mercurochrome

D. E. H. CLEVELAND (*Canadian Med. Assoc. Journ.*, February, 1931, p. 272) reports a case of mercurialism in an infant which followed the application of a 4 per cent. solution of mercurochrome 220 soluble. Six days after birth groups of vesicles developed around the ears and neck, and the application of mercurochrome was ordered, associated with ultra-violet irradiation. After rupture of the vesicles slight suppuration ensued, but healing followed. Subsequently more vesicles appeared on the chest, one arm, and one leg, and a transient cyanotic swelling of the right thumb and index finger developed, with a vivid red rash over the whole body. There was a definite blueness of the extremities, and the child held the neck and body in a hyperextended position. There was much frothy saliva, and the mucous membrane of the mouth was reddened. There was a trace of albumin in the urine, but no casts or red cells; the weight decreased a little. The mercurial applications and irradiation were stopped, and the infant steadily improved. Cleveland criticizes the use of irradiation in dermatology as a routine procedure, but thinks that in the present instance it was in no way to blame. He considers this a definite case of general poisoning following the external application of mercury, which indicates that there is some risk attending the employment of mercurochrome in this way, a point to be remembered in prescribing it for such a common disorder as impetigo contagiosa.

377 Treatment of Pernicious Anaemia

K. GUTZEIT and J. HERRMANN (*Münch. med. Wöch.*, February 13th, 1931, p. 266) have administered daily by the mouth to three patients with pernicious anaemia 75 to 100 c.mm. of gastric juice obtained from dogs after it had been allowed to act on 250 grams of muscle for one hour at 37° C. They obtained a marked reticulocyte reaction with subsequent rise in the red cell count and the haemoglobin percentage after four to eight days. A similar

reaction was obtained by giving a special pepsin preparation, but only after this had been allowed to act on muscle for one hour at 37° C. The authors assert that the ferment of ventriculin does not contain the anti-anaemia substance, and that the powdered extract from the membrane of the fundus always gave a quicker and more certain reaction to reticulocytes and red cells than the extract obtained from the pyloric mucous membrane. Powdered extract obtained from the small intestine of the pig was tried in one case of pernicious anaemia without effect.

378 Tryparsamide in Neurosyphilis

J. SPITZ (*Urol. and Cut. Rev.*, February, 1931, p. 122), who records two illustrative cases of its use in men, aged 36 and 43 respectively, states that tryparsamide, the sodium salt of N-phenyl-glycine-amido-*p*-arsonic acid which was discovered by Jacobs and Heidelberger in 1915, has an affinity for the central nervous system and exerts a general tonic effect. It is, however, of little value in the treatment of syphilitic conditions other than those of the central nervous system, but it is most effective in the early stages of tabes and general paralysis. Its toxicity is slight, and when toxic sequels such as arsenical dermatitis occur they soon clear up. The greatest danger is optic neuritis. A careful ophthalmoscopic examination should therefore be made before beginning the use of the drug, and a close watch should be kept for the earliest manifestation of retinitis during treatment.

Laryngology and Otology

379 Laryngeal Complication of Quinsy

G. MARTUSCELLI and M. ALEMI (*Arch. Ital. di Otol., Rinol. e Laryngol.*, January, 1931, p. 1) record a personal case with a review of the literature dealing with involvement of the larynx secondary to quinsy. Their patient was a man, aged 34, who on the day following evacuation of a peritonsillar abscess developed difficulty in breathing. Laryngoscopic examination revealed oedema of the vestibule of the larynx, especially of the arytenoids and aryepiglottidean folds. Throat swabs showed a mixed growth of staphylococci and streptococci. Ice was applied externally and the throat was sprayed with carbolic acid. As the symptoms became worse the next day, free incisions were made in the affected parts with Tobold's knife, and intragluteal injections of antipyogenic stomosine were given; in four days the symptoms subsided, and in about a week the patient made a complete recovery. The authors have collected four other cases of quinsy with laryngeal complications from the literature, of which two were fatal and one recovered after tracheotomy; the issue in the fourth instance is not recorded.

380 Involvement of the Acoustic Nerve in Encephalitis

E. WODAK (*Rev. de Laryngol., d'Otol. et de Rhinol.*, December 15th, 1930, p. 681) examined all the cases of epidemic encephalitis admitted to the German Neurological Clinic at Prague from 1925 to 1927 and found that almost every patient had had at some period of his illness involvement of the eighth cranial nerve. The vestibular division was most commonly affected, and a few cases of both divisions being attacked were seen, but in no instance was involvement of the cochlear division alone observed. The affection may be either a hyper-excitability or a hypo-excitability, and may involve one or both sides. The patient complains of vertigo, nausea, and vomiting, and, if both divisions are involved, of deafness and tinnitus. Spontaneous rotary nystagmus is observed. The author was also impressed by the differences noted in the responses to the caloric and rotatory tests in the same patient. Hyper-excitability to one stimulus may coexist with hypo-excitability to the other. Differences between the tonic reflexes and the nystagmus were also noticed in some cases during the rotation tests. A number of cases were examined which presented the post-encephalitic condition of ocular muscle spasm, pseudo-Parkinsonian retropulsion and propulsion, and spasmodic torticollis. It was found that all these signs were altered or abolished if the vestibular nerve was stimulated by either hot or cold caloric tests, and the author claims that these well-known post-encephalitic phenomena are always due to disordered labyrinthine reflexes. Cases have been seen which presented no other symptoms than the vestibular. Labyrinthine symptoms often persist in patients who have made an otherwise complete recovery. They complain of sudden giddiness, often associated with change of position of the head, and simulating otolithic disorder. There are often long periods of freedom from symptoms, but each relapse is more severe than its predecessor.

381 Intrinsic Carcinoma of the Larynx

W. O. JOHNSON (*Amer. Journ. Surg.*, January, 1931, p. 16) emphasizes the importance of early diagnosis and treatment of carcinoma of the larynx. The condition occurs most often after the 30th year in men, and constitutes 98 per cent. of the malignant lesions of the larynx; of these 96 per cent. are of the squamous-cell type, and are of Group 4 malignancy. The initial symptom in 90 per cent. of cases of carcinoma of the larynx is a persistent hoarseness, with pain, dryness, and dysphagia as later symptoms. Direct laryngoscopy is of value where the diagnosis is in doubt. Surgical treatment should be undertaken as soon as possible, before the vocal cord has become immobile through the penetration of the subadjacent muscles by the neoplasm. Immobility is usually dependent upon infiltration posteriorly into the base of the arytenoids, with extension of the growth across the anterior commissure, posteriorly to the ventricular band on the epiglottis, and downwards to the cricothyroid membrane. When this extension is present the lymphatic channels are involved, and metastasis becomes probable, with a poor prognosis. Laryngo-fissure should be performed only in very incipient cases in the anterior quarter of the cord, where much normal tissue can be removed with the growth. For the great majority of cases laryngectomy is the operation of choice. Local anaesthesia by novocain block and infiltration has been found to be successful, and general anaesthesia should be avoided whenever possible. Careful pre-operative and post-operative treatment is of the greatest importance. The mortality after laryngectomy was only 3 per cent.; it was found that 70 per cent. of patients suffering from intrinsic carcinoma of the larynx could be cured by this means, and were able to return to their normal life and occupation.

Obstetrics and Gynaecology

382 The Diagnosis of Pregnancy

According to J. K. COUCH (*Med. Journ. of Australia*, January 24th, 1931, p. 99) one of the most reliable signs of pregnancy is that discovered by Jacquemin in 1836, which consists in the blue staining of the vulva, usually most marked around the meatus, in the vestibule, and extending up the anterior vaginal wall. It commences about a month after the beginning of pregnancy, and becomes more marked with its advance. It disappears if abortion ensues or the ovum dies. Couch has also found a violet discoloration of the cervix, most marked at the os and gradually fading upwards. These colour changes must be observed by daylight; they are said to be absent in other forms of uterine enlargement. Other of the more trustworthy indications of pregnancy are amenorrhoea, confirmed by increase in the size of the uterus to a corresponding degree, marked anteflexion, softening of the cervix and of the uterine fundus, especially anteriorly, and breast signs in the primipara, though not in the multipara. Couch believes that the most useful diagnostic evidence of an early tubal mole is the cessation of menstruation at the proper time, and then its reappearance for a couple of weeks, though not profusely. He thinks that many early ectopic pregnancies are undiscovered, the patients recovering without an operation

being indicated or required. Although the uterus enlarges in a case of ectopic gestation, it never exceeds the size of a three months' pregnancy, even when the ovum is at full term.

383 Lymphocytosis associated with Ovarian New Growth

H. M. WINANS (*Amer. Journ. Med. Sci.*, February, 1931, p. 251) reports a case of leukaemia developing apparently in association with the appearance of a pseudo-mucinous cyst of the right ovary and a papillary adenoma of the left ovary. A married woman, aged 29, was admitted to hospital with a normal blood picture and a respiratory infection with Vincent's organisms which yielded promptly to treatment. A cyst of the right ovary was discovered by a radiographical examination, and at the operation a papillary ovarian adenoma on the other side was found and removed also. Abdominal tenderness had caused attention to be directed to this part of the body, and simultaneously with its appearance there had been a leucocytosis of over 18,000 per c.mm., with a lymphocyte percentage of 85. Following the operation the leukaemic picture gradually diminished until the blood count returned to the normal. Winans is satisfied that the original infection with Vincent's organisms was not the cause of the lymphocytosis; he thinks it possible that there might have been some degree of peritoneal irritation associated with the ovarian growths, and that this affected the blood. Alternatively, the growths themselves might have been responsible, but no evidence in support of this view was obtained.

384 Salpingostomy for Sterility

According to W. T. MATWEJEWA (*Zentralbl. f. Gynäk.*, January 31st, 1931, p. 302) salpingostomy is capable of restoring tubal function in a not inconsiderable number of cases, including some in which the morbid anatomical conditions are long-standing and extensive. At the operation, which must be deferred until all acute inflammation has subsided, it is essential to perform ventrofixation simultaneously. The combined procedure, employed at the author's clinic on forty-five occasions during the last two years, and sometimes preceded by partial resection of the tube, has so far been followed by five pregnancies, two after sterile marriages lasting nine and five years respectively. The operation should be followed by periodical insufflation of the tubes.

Pathology

385 Etiology of Blood Transfusion Reactions

J. BORDLEY (*Arch. Int. Med.*, February, 1931, p. 288) describes a delayed or prolonged reaction following blood transfusions in 17 cases, which he believes was due to the injection of incompatible blood. The signs and symptoms develop from severe functional renal damage. Most of the patients were relatively young adults. Anaemia was present in all, but this and the patients' general condition had little influence on the occurrence of the reaction or its outcome. The reaction presents the following characteristic features. Immediately after transfusion a sharp febrile reaction occurs, followed frequently by haemoglobinuria, and invariably by suppression of urine. For several days afterwards there is symptomatic improvement, but continued oliguria. After this interval the delayed reaction develops rapidly, commencing with agitation or drowsiness, which is replaced by evident uraemia. Convulsions and coma may supervene. The outcome is frequently fatal; 11 of the 17 patients died. Recovery is associated with diuresis; death occurs in uraemia. At the necropsy the kidneys are swollen; the tubular epithelial cells contain droplets of pigment, and show advanced degenerative changes; the tubular lumina are filled with various cells, blood pigment, and debris. Small hepatic necroses are generally found. Four possible explanations of the mechanism by which incompatible blood damages the kidneys are discussed—namely: (1) by mechanical blockage of their tubules; (2) by a local reaction of an anaphylactic nature; (3) a metabolic disturbance; and (4) damage of the renal substance by toxic substances set free in the blood. The daily output of urine greatly aids in prognosis; haemoglobinuria is of far less prognostic significance than the amount of urinary excretion. The delayed reaction is not rare. In addition to the detailed reports of the present cases, brief mention is made of several others which have been recorded.

386 The Titre of Isoagglutinating Serums

P. GIOVANNI and C. ANGELERI (*Rif. Med.*, January 5th, 1931, p. 8) consider that for the determining of blood groups it is essential to use serums of high activity, and describe a method of estimating the titre of isoagglutinating serums. They also recommend the determination of the panagglutinating content. Small amounts (4 to 5 c.cm.) of blood are removed from a series of persons of Groups II and III; preliminary hanging-drop tests are made with them. The titres of the positive serums are estimated as follows. With an ordinary red-cell pipette, serum is drawn up to the mark ½, blood cells of suitable group to mark 1, and sodium citrate to mark 101, the serum being diluted 100 times. After mixing, the contents of the pipette are blown out into a haemolysin tube, kept at 37° C. for an hour, and then examined microscopically in hanging drops. This procedure is repeated with the same serum, and in the case of several individuals of the same group. The positive serums indicate that a titre above 1 in 100 is reliable for determining blood groups. To estimate the panagglutinin content a white-cell pipette is used. The serum to be tested is drawn up to mark 1, red cells (from the same group or from Group I) to mark 3, and sodium citrate to mark 11, the serum being diluted 1 in 10; the number of red cells is not excessive, or likely to mask the presence of panagglutinin. The contents of the pipette are blown into a haemolysin tube, placed on ice for an hour, and then tested microscopically in hanging drops. Safety is ensured when no trace of agglutination is observed.

387 Seasonal Variations in Resistance to Disease

F. MAIGNON (*C. R. Soc. de Biologie*, February 20th, 1931, p. 445), discussing the increased susceptibility of animals at different times of the year to the action of certain viruses, toxins, and chemical substances, draws attention to the work that he has carried out on the seasonal alteration in metabolic activity. He finds that, in the dog, muscular glycogenesis reaches its first maximum in the spring, and a second less marked maximum in the autumn; in the summer and winter it is at a minimum. Similar observations have been made on the carp and the guinea-pig. The author has also found that in the dog and the guinea-pig the activity of respiratory combustion, or the oxidation of organic compounds, displays the same seasonal variations, being at a maximum in the spring and autumn, even in animals kept at a uniform temperature and fed on a uniform diet. It is noteworthy that these maxima coincide with the periods of activity of the genital glands. That these glands have an effect on nutrition is indicated by the fact that the titre of glycogen in the muscles is always higher in males than in females; castration of the male lowers the titre to that of the female, while the injection of testicular extract into the normal but not the castrated male raises the glycogen titre. Maignon has further observed that white rats fed exclusively on ovalbumin and mineral salts survive for four to six weeks in the summer and winter, while they die in three to six days in the months of May and November. The addition of vitamins to the diet does not modify this result. He concludes, therefore, that the seasons influence muscular glycogenesis, respiratory combustion, and nutrition as a whole, altogether apart from any change in temperature; that in spring and autumn nutritional activity reaches its maximum; and that at these times the susceptibility to infections and intoxications is increased.

PERCAINE "CIBA"

Trade Mark Registered

The New Local Anæsthetic for Regional, Infiltration, Surface and Spinal Anæsthesia

Acts in extreme dilution (0·5—2 : 1000).
Produces anæsthesia of unattained intensity and duration.
Not a narcotic. Economical in use.
Belongs chemically to a class entirely different from cocaine and its derivatives.

Vide *British Medical Journal*, March 15, 1930, pp. 488-9, and 495-6, and April 5, 1930, pp. 660-70. *The Lancet*, March 15, 1930, pp. 573-4 and 587. *British Journal of Anæsthesia*, April & July, 1930. *Proceedings of the Royal Society of Medicine*, May, 1930, pp. 919-928. *British Journal of Urology*, June, 1930, pp. 129, 130 and 179.

THE CROWNING ACHIEVEMENT

U.G.B. MEDICAL BOTTLE *Service*

DURING the past ten years at tremendous expense, a very wide range of automatic machine mould equipment has been built up by the U.G.B. to cater for practically every bottle requirement of the Chemist and Dispenser. New and attractive shapes are now being added from time to time.

The Crowning Achievement was the introduction of the "Washed and Sterilised Ready-to-Use Package" which is daily growing in demand.

Only a small percentage of the actual cost of this service is passed on to the customer.

Supplied either for corks or complete with Rustless White Enamelled Screw Caps.

Once you have experienced the value and convenience of this U.G.B. Service you will use nothing else. Try it NOW and be prepared for the WINTER.

Obtainable from all leading Wholesalers.

RHEUMATOID and OSTEO-ARTHRITIS

Amidst the recognised difficulties in treatment of advanced cases of Rheumatoid and Osteo-Arthritis it is not generally realized that many patients have been restored to active life after being bedridden, suffering great pain for years, by Hoefftcke's Ambulatory Extension Treatment.

Many cases have been described by eminent medical men, some results of which are shown below.

FIG. 1.—December, 1921.

Case of Mrs. H., aet. 35.

FIG. 1.—Shows the knee-joint fixed in a position of partial flexion; patella ankylosed.

FIG. 2. — Shows after an interval of 9 years the improvement which resulted from 3 years' extension treatment—the complete restoration of the tibio-femoral joint which permits of free and painless flexion and extension.

This case was one of exceptional severity. In the average case the Extension Walking Appliance can be discarded in one or two years from the time of its first application.

FIG. 2.—April, 1930.

FIG. 3.—December, 1921.

FIG. 3.—Shows the irregularity of the outline of the articular surfaces as seen from before backwards. The interval between the bones is practically obliterated.

FIG. 4.—Shows the joint in an antero-posterior plane. Note the restoration of the outlines of the articular surfaces and the formation of a practically normal interval between the bones.

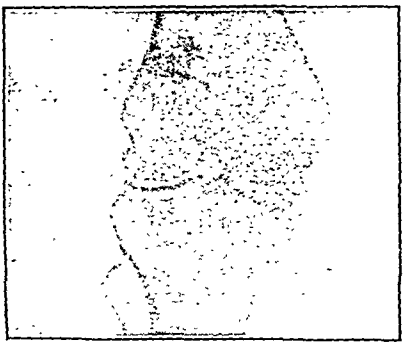

FIG. 4.—April, 1930.

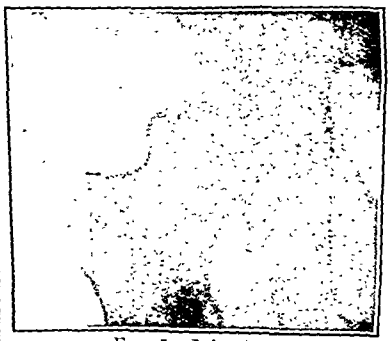

FIG. 5.—July, 1929.

Case of Mr. S., aet. 68.

FIG. 5.—Shows the hip-joint practically ankylosed in the *adducted* position. Patient hardly able to walk with great pain.

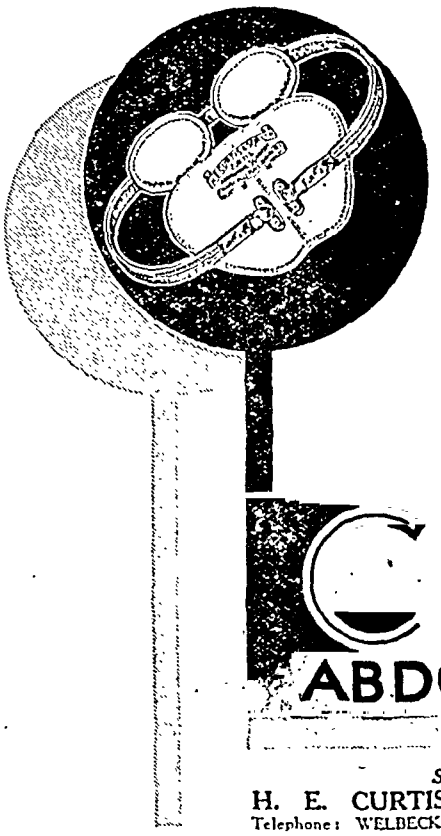
FIG. 6. — Shows spike absorbed; cavity filled in; head of femur covered with new cartilage, resulting in free abduction with full painless movement in the joint.

FIG. 6.—February, 1931.

Particulars and illustrations of this treatment will be forwarded on application, and original radiograms of these and other cases can be shown

by

CAREL A. HOEFFTCKE, 7, Harley Street, London, W.1.



Comfortable, and Correct Support

Assured to all sufferers from abdominal ptosis who wear the Curtis Abdominal Support, Model No. 1. The principle of this support—that of anterior posterior support—has been proved by scientific research to be the most efficient. There is no circumferential pressure, hence the wearer's freedom of movement is in no way restricted. There is no cramping or binding of the hips. It is light in weight, and easy to apply. There are no complicated fastenings.

IN USE IN MOST OF THE LONDON HOSPITALS.

"VARIBAN"

Elastic Plaster BANDAGE

MADE from a specially woven selvedge material, possessing very elastic properties, evenly spread with an Antiseptic Zinc Oxide Paste. *Self-adhesive, readily conforming to* the shape of the limb, and when carefully applied forms an even surface dressing which will not crease or slip. Firm support. Easy to remove. Extensively used in many well-known hospitals for the treatment of VARICOSE ULCERS, VARICOSE VEINS, SURGICAL and ORTHOPAEDIC CASES, etc. Their application for treatment of Varicose Ulcers, etc., does not necessitate the patient lying-up; in fact, permits the continuance of light duties. Ensures rapid healing.

FOR DEAFNESS

Doctors prefer "ARDENTE" because—

"ARDENTE" STETHOSCOPE.

Mr R. H Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, as evidenced by the interest shown at the last B.M.A. Meeting.

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises, giving inconspicuous hearing.
4. It conveys sounds from varying ranges and angles.
5. It is entirely different, uncopiable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf through various causes.
7. It is helpful for conversation, music, talkies, wireless, home, office, public work, and sports.

FREE HOME TESTS
arranged for Doctors and Patients.
Medical Prescriptions made up to the minutest detail.

MEDICAL REPORTS.

Commended by all leading medical journals.—Mr. Dent will be happy to send full particulars and reprints on request.

TO COUNTER ACIDOSIS

As SALVITAE contains 59% of Potassii et Sodii Citro-Tartras and 39% of Sodii Sulphas it is of great value both in maintaining health and in the treatment of disease, through eliminating deleterious nitrogenous products and favourably influencing circulation, glandular secretions, peristalsis, and metabolism.

The fruit acids of SALVITAE are converted in the system into potentially basic alkaline carbonates, thus enabling the blood to keep the uric acid compounds in solution, and facilitate their removal.

NEW SUITS FOR SPRING

TERMS £1 PER MONTH

BRIGHT sunshine shows up the shiny and shabby spots now that *overcoat days are being left behind.* Apart from being a necessity, a new Spring suit gives increased confidence and presence to the wearer especially when the worry of paying for it is banished . . . . *At Keith Bradbury's* good cloth is tailored into attractive garments by the deft hands of West End craftsmen—*and all financial worry is avoided* by the arrangement of systematic payments out of income FROM £1 PER MONTH to meet the individual requirements of customers. . . . . A FREE VALETING SERVICE is provided for sponging, pressing and repairing all garments after purchase, as often as is desired, and the same care is given to every suit irrespective of the initial cost . . . . A trial is solicited on the understanding that if any garment is not to *your satisfaction, you need not accept it—and you will* have incurred no obligation.

Lounge or Plus-four suits from 5 gns.
Flannel trousers from 21/-. Blazers from 45/-.
Dinner and Evening Dress from 6 gns.
Catalogue and patterns gladly sent free on request.

Coats for Spring
Ready to wear from 3 gns.
To measure from 4 gns.

Every engine has a definite limit to its possible output and the best sparking plug in the world cannot improve the output beyond that limit, but it is surprising how many engines are run below their best performance owing to the use of unsuitable plugs.

Until you have tried a new set of

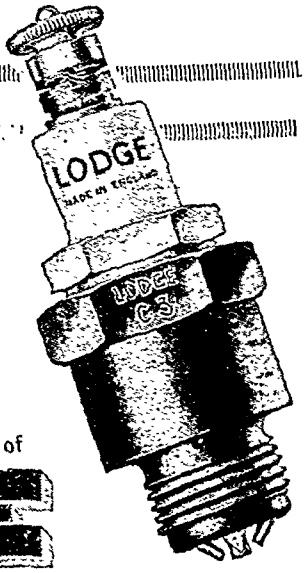
LODGE

SPARKING PLUGS

you cannot be sure that you are getting the best results out of your engine.

They can be bought at all good garages.

LODGE PLUGS LTD., RUGBY.



LODGE C3

Apply, Miss OLIVER. Tel.: Hindhead 27.

CHEADLE ROYAL, CHEADLE, CHESHIRE.

This Registered Hospital for MENTAL DISEASES, with the seaside branch Glan-y-Don, Colwyn Bay, is for the treatment and care of PRIVATE PATIENTS of the UPPER and MIDDLE CLASSES. Voluntary, Temporary, and Certified Patients received.

For terms, etc., apply to the Medical Superintendent, J. A. C. ROY, M.B., who may also be seen in Manchester by appointment.
Telephone: 2231 GATLEY.

ST. ANDREW'S HOSPITAL FOR MENTAL DISORDERS, NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy *is a feature of this branch, and patients are given every facility for occupying themselves* in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM.

HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary and Temporary Patients received.

Tel.: 64117. *For terms, etc., apply to the Medical Superintendent.*

BRITISH SPAS
ARE BEST
and membership of the British Spas Federation is a guarantee of efficiency

AT British Spas, treatment is only given (except in a few minor cases) upon medical prescription.

At British Spas the staffs are educated and properly trained and, in some cases, medically trained and medically certificated.

Equipment and administration are thoroughly up to date and scientific. Every new treatment is tested and reported upon before being adopted.

British Spas are also remarkably fortunate as regards situation, scenic beauty and pure air. These factors, combined with the social amenities of a home town, aid the cure considerably.

BATH Hot Springs (120° F.) Radio-active. Royal Baths extensions now open.

BRIDGE OF ALLAN Saline Water. Rich Calcium Bromide and Iodine Content.

BUXTON Radio-active Mineral Water. New Natural Baths. 3 Guineas Course.

CHELTENHAM Five Natural Waters. *Modern* Baths.

DROITWICH The Brine Baths Spa in charming Worcestershire.

HARROGATE 88 Waters. 100 Treatments. Medically *certificated staff.*

LEAMINGTON Advanced Spa Treatment. Saline Springs.

LLANDRINDOD WELLS The Modern Welsh Spa.

TREFRIW WELLS Rich Sulphate Chalybeate Waters.

WOODHALL SPA Bromo-Iodine Waters. Pinewoods. Restful Air.

¶ *A New Medical Handbook is being published, specially prepared for the use of the medical profession. A copy will gladly be sent you if you will write to the Hon. Secretary, Box 1, British Spas Federation, Pump Room, Leamington Spa, or to the Managers of any of the Spas here mentioned.*

ANNOUNCEMENT BY BRITISH SPAS FEDERATION

The MUNDESLEY SANATORIUM

The newly opened central building makes the Mundesley Sanatorium the best equipped building in England for the cure of Tuberculosis. All the bedrooms have hot and cold running water, electric light, and wireless head-phones. The new public rooms are spacious and comfortable.

Resident Physicians:
S. VERE PEARSON, M.D.(Cantab.), M.R.C.P.(Lond.).
L. WHITTAKER SHARP, M.B.(Cantab.)
ANDREW MORLAND, M.D., M.R.C.P.(Lond.).

For all information apply:
THE SANATORIUM, MUNDESLEY, NORFOLK.
(Telephone: Mundesley 4.)

The buildings face S.S.W. and are sheltered from the sea by a pine-clad ridge. The sunshine record and dry air complete a perfect site. The medical equipment is of the latest kind, and there is a day and night nursing staff.

TOR-NA-DEE SANATORIUM

Candidates will be required to carry out Medical Inspection of School Children and Child Welfare work and perform such other duties as may be allotted as Assistant to the Medical Officer of Health and School Medical Officer.

The person appointed will be required to devote his whole time to the duties, and will not be allowed to engage in private practice. Salary will be at the rate of £600 per annum, rising to £700 by £25 per annum.

A deduction of 5 per cent will be made from the salary in accordance with the provisions of the Local Government and Other Officers Superannuation Act, 1922, which has been adopted by the Council, and the appointment will be subject to passing the Council's medical examination in connection therewith.

Copies of application form and terms of appointment can be obtained from the undersigned, to whom applications, accompanied by copies of not more than three recent testimonials, must be delivered not later than April 21st.

THOMAS ORR, M.D., D.Sc.,
Town Hall, Medical Officer of
Ealing, W.5. Health.

Borough of Cambridge.

Applications are invited from fully qualified Medical Practitioners under 35 years of age for the post of Whole-time ASSISTANT SCHOOL MEDICAL OFFICER and ASSISTANT MEDICAL OFFICER OF HEALTH. Salary £500 per annum, advancing by annual increments of £25 to £700; previous experience in a similar capacity will be taken into account in assessing the commencing salary.

Applicants must have had at least three years' practice since qualification, and must have had experience in the correction of errors of refraction. A Diploma in Public Health will be an additional qualification.

The successful applicant will be required to undergo a medical examination, and to contribute to the Local Government and Other Officers Superannuation Scheme.

A list of duties and application forms may be obtained (on receipt of a stamped addressed foolscap envelope) from the Secretary for Education, The Guildhall, Cambridge, to whom applications, with copies of not more than three recent testimonials, must be sent not later than Thursday, April 23rd

The Guildhall, C. H. KEMP,
Cambridge. Town Clerk.
April, 1931.

City of Birmingham.

DUDLEY ROAD HOSPITAL.

JUNIOR ASSISTANT MEDICAL OFFICERS (Male).

Applications are invited from fully qualified Medical Practitioners for appointments as Junior Assistant Medical Officers (male) at the Dudley Road Hospital, Birmingham.

The Hospital accommodation is fixed at 926 beds, divided into Medical, Surgical, Children's Infectious, Maternity, Gynæcology and Obstetric Sections. There are completely equipped Pathological and Biochemical Laboratories, Deep Therapy, X-Ray, Electrical Massage, Sunlight and Dental Departments. Approximately 5,000 operations are performed annually.

The appointments will be for a period of six months in the first instance, but may be extended at the end of that time for a further period not exceeding six months.

The persons appointed will be required to assist at operations, to administer anæsthetics, and undertake casualty work and such other duties as may be assigned to them by the Medical Superintendent.

The salaries attached to the appointments will be at the rate of £200 per annum, together with full residential emoluments (rations, apartments, laundry, and attendance).

The officers appointed will be required to pay to the Council all fees, allowances, and emoluments (other than the foregoing) received by them.

Further particulars of the appointments may be obtained from the Medical Superintendent, F. W. ELLIS, Esq., M.D., *F.R.C.S., Dudley Road* Hospital, Birmingham, to whom applications, stating age, experience, and qualifications, accompanied by copies of recent testimonials, should be forwarded not later than Thursday, May 7th.

F. W. ELLIS, Esq.
Dudley Road Hospital, Birmingham.

City of Liverpool.

APPOINTMENT OF MEDICAL OFFICER OF HEALTH.

The Corporation invite applications for the position of Medical Officer of Health for the City and Port of Liverpool and Medical Officer to the Education Authority at a salary of £1,800 *per annum*. The duties will be those prescribed by statute, subject to such variations in administration as the City Council may from time to time direct, and will include the general supervision of the Municipal Hospitals.

The officer appointed will be *required to* devote his whole time to the duties of the office, and will not be allowed to engage in private practice, and all emoluments out of public moneys which may be payable to or received by him will have to be paid to the Corporation.

The officer appointed will hold office subject to the Standing Orders of the Council, and the appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922. He will also be required to reside within the City.

Canvassing of members of the Council will be regarded as a disqualification.

Particulars of duties may be obtained on application to the Town Clerk.

Applications, stating age and qualifications, with copies of testimonials (not exceeding three) endorsed "Medical Officer of Health," addressed to the Chairman of the Health Committee, under cover to the Town Clerk, Municipal Buildings, Liverpool, must be delivered at the *Town Clerk's Office, Liverpool, not later than* May 2nd.

Town Clerk's Office, WALTER MOON,
Liverpool. Town Clerk.
April 10th, 1931.

City of Nottingham.

The Health Committee invite *applications* from duly qualified Medical Practitioners for the post of MEDICAL OFFICER to the CITY INFIRMARY, Hucknall Road, Nottingham.

The Hospital has 900 beds for the treatment of all classes of sick persons. It is a recognized Training School for Nurses, and is equipped with all modern requirements. Candidates must possess General Hospital experience, and preference will be given to those having Poor Law experience.

The salary will be £350 per annum, rising by annual increments of £25 to £450, with rations and furnished apartments. The successful candidate will be required to contribute to the Corporation's Superannuation Fund.

Applications, on forms to be obtained from the undersigned, with copies of not more than three recent testimonials, and endorsed "Medical Officer," should be forwarded not later than May 2nd.

(Signed) W. J. BOARD,
Guildhall, Town Clerk.
Nottingham. April 1st, 1931.

City and County of Kingston-upon-Hull.

APPOINTMENT OF ASSISTANT *TUBERCULOSIS OFFICER.*

The Corporation invite applications from Medical Practitioners (male), of not more than 40 years of age, for the appointment of Assistant Tuberculosis Officer, at a commencing salary of £600 per annum, rising by annual increments of £25 to a maximum of £700. Applicants should have held, prior to April 1st, 1930, an appointment as Tuberculosis Officer, with the approval of the Minister of Health, or should, subsequent to qualification:

(1) Have had at least three years' experience in the practice of their profession;
(2) Have spent in general clinical work a *period of not less than eighteen months*, of which not less than six months have been spent in a hospital as resident officer in charge of beds occupied by general medical or surgical cases; and
(3) Have received special training, for a period of not less than six months, in the diagnosis and treatment of tuberculosis.

The candidate appointed will work under the administrative supervision of the Medical Officer of Health, and will be immediately responsible to the Senior Tuberculosis Officer.

This appointment is a designated post under the Local Government and Other Officers Superannuation Act, 1922.

Application forms may be obtained from the undersigned, to whom they should be returned not later than April 27th.

Guildhall, Hull. April, 1931. W. M. FRAZER, Medical Officer of Health.

Staffordshire County Council.

ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH.

Applications are invited from Medical Practitioners holding the Diploma of Public Health for the above post. Candidates should have had at least three years' experience in the practice of their profession subsequent to qualification. Preference will be given to those who have held residential Hospital appointments.

The person appointed will work under the direction of the County Medical Officer, and the duties of the office will include School Medical and Maternity and Child Welfare work, in addition to such general public health work as may from time to time be prescribed.

The salary will be at the rate of £600 per annum, rising to £800 per annum by annual increments of £50, subject to a deduction of 5 per cent established under the Local Government and Other Officers Superannuation Act, 1922. Travelling expenses will be paid by the Council.

The appointment will be subject to three months' notice on either side.

Forms of application may be obtained from the undersigned, and should be returned by April 22nd, together with copies of not more than three testimonials.

County Buildings, Stafford. March, 1931. EUSTACE JOY, Clerk of the County Council.

Enfield and Edmonton Joint HOSPITAL BOARD,

Winchmore Hill, N.21.

APPOINTMENT OF RESIDENT MEDICAL SUPERINTENDENT.

The Board invite applications for the appointment of a Resident Medical Superintendent, at the salary of £700 per annum, rising by £50 annual increments to £900, subject to a deduction therefrom of five per cent. for superannuation under the Local Government and Other Officers Act, 1922. Applicant must not be over 40 years of age, and should have had experience as a Resident Medical Officer in an Isolation Hospital; experience of Ear, Nose, and Throat work an advantage. Forms of application may be obtained from me, and should be returned not later than noon on Friday, May 1st.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)
(FOUNDED 1880.)

12, Stratford Place,
Oxford Street, W.1.

Tele. Address: Triform, Wesdo—London.
Telephone: Mayfair {1782 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION have every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of fully qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.

Under the personal directorship of Dr. J. FIELD HALL and J. C. NEEDES

who have both had many years' experience as Medical Transfer Agents.

The commission chargeable in respect of any practice or partnership in Great Britain placed exclusively in the hands of this Agency has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being fifty pounds (£50).

No charge is made to Principals for the introduction of Locum Tenens or Assistants.
Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.

1. DEATH VACANCY.—SOUTH-EAST COAST.—In a favourite Watering-place, very old-established upper and middle-class non-panel and non-dispensing PRACTICE. Receipts last year £2,450. Very good house. Rent on lease £140 p.a. Moderate premium accepted. Purchaser should be a Surgeon as part of the income is derived from this source, and late Incumbent was on staff of Hospital.
2. LONDON, S.W.—PARTNERSHIP.—A one-third share is offered in a very sound chiefly middle-class Practice, producing last year about £5,500. Panel of 1,600 and increasing rapidly. Fees from 2/6. Suitable house can be rented on lease. Premium 2 years' purchase.
3. EASTERN COUNTIES.—Within 60 miles of London and near County Town. — Very old-established mixed-class PRACTICE in delightful district (pop 6,000 to 7,000), worth last year nearly £800, including appts. £170 and panel over 150. Capable of considerable increase for reasons which can be explained. Excellent house, with beautiful garden and several acres of ground. Price, freehold, £1,800. Premium only £800. Sport of all kinds.
4. GLOUCS.—PARTNERSHIP, with preliminary Assistantship of 2 to 3 months.—A one-third share is offered in a well-established Practice, producing about £2,250 p.a., with substantial panel and good appointments. Situated in beautiful district round country town affording excellent sporting facilities. Suitable house (or rooms to commence) can be obtained. Premium 2 years' purchase.
5. PARTNERSHIP.—MIDLANDS.—Prosperous Town within 80 miles of London.—A one-third or five-twelfths share is for disposal owing to the retirement of the second of three partners in an exceptionally sound mixed-class Practice. Average gross cash receipts £3,300 p.a., including panel of 1,000. Fees 2/6 to 25/-, medicine extra. Premium only 1½ years' purchase for quick sale, owing ill health.
6. ESSEX.—PARTNERSHIP.—Practice is situated in developing neighbourhood, within easy reach of town. A one-half share is offered in steadily increasing Practice bringing in nearly £2,700 p.a., including panel of 1,000. Very nice house, with three reception, six bedrooms, etc., and good garden. Price £1,400, part on mortgage. Premium 2 years' purchase. Good scope for Surgery.
7. SOUTH WEST OF ENGLAND.—County Town.—PARTNERSHIP, after preliminary Assistantship.—A share representing about £600 p.a., with increase later and ultimate succession, is offered in a very well-established Practice, having substantial panel. Premium 2 years' purchase. Ingoing partner should be experienced and pref. English or Scotch Graduate.
8. PARTNERSHIP.—NORTH-WEST COAST.—Popular Seaside Resort.—The third share, with option up to half in 3 years, of very old-established non-dispensing good middle-class Practice, averaging over £4,200 p.a. (last year £4,567), including panel £300. Held many years by Vendor. Visits 3/6 to 21/-. Good house available on lease. Premium 2 years' purchase, part by instalments. Ingoing partner should be about 30 years of age and able to do minor surgery. Hospital in town.
9. DEATH VACANCY.—NORTH WALES.—Pleasant Coastal Town amidst beautiful surroundings. — Old-established Practice, averaging over £1,800 p.a., including appt. worth £90 and panel of 400. Visits 3/6 to 10/6, occasionally 21/-. Large house in 1/2 acre of garden. Price, freehold, £3,500, or might be rented. Can be easily divided, leaving professional accommodation, 2 sitting, 6 bedrooms, bathroom, etc., at rental of £80. Premium £2,000. Excellent scope for surgery. Good Hospital.
10. LONDON, WEST . . . . and increasingly mixed-class PRACTICE, . . past 12 months £1,790, including panel of . . No midwifery. House in excellent repair, contains 2 reception, 4 bedrooms, bathroom, etc. Price for freehold £2,500. Premium 2 years' purchase.
11. CORNISH RIVIERA.—Old-established PRACTICE, in very favourite resort, having exceptionally mild climate. Income about £1,150, including panel of 436, and appts. worth about £40 a year. Fees 3/6 to 21/-. No opposition within 4 miles. Well-situated house, with 2 reception, 6 bedrooms, etc., and professional rooms. Good garden. Rent on lease, £52 p.a. Premium £1,650.
12. HANTS.—Easily worked Country PRACTICE within about 60 miles of London. Receipts for the last 12 months over £1,000, with panel of 450. Visits from 7/-. Nice house, with 3 reception, 6 to 7 bedrooms, etc. Good professional accommodation. Large garden. Freehold for sale. Premium 1½ years' purchase.
13. LONDON, E.C. (near Holborn Circus).—Old-established mainly working-class PRACTICE, averaging over £700 p.a. (last year £760), including recently started panel of 360. Fees from 2/-. No midwifery. Six-roomed house, with good professional accommodation. Rent on lease £95 p.a. Premium £1,000.
14. LONDON, EAST.—Well-established mixed-class PRACTICE, averaging about £1,150 p.a., including panel of 1,400. Small house, with 1 reception, 2 bedrooms, etc., and 3 professional rooms. Rent on lease £13 per quarter. Premium £2,000.
15. SOUTH AFRICA.—Within 8 hours of Durban.—Rapidly increasing PRACTICE in very pretty township near sea coast, producing last financial year over £1,700, including appt. £120. Practically all fees, which are good, are paid in cash. Opposition negligible. Bungalow residence in about one acre of ground. Rent £84 on lease. Premium £1,500, to include furniture, drugs, instruments, and motor car (£1,325 without latter), payable £1,000 down and balance by easy instalments. Excellent climate and sport.
16. NORTH . . . —A one third share is offered in a good . . . . . ieing over £1,700 p.a., including panel of : . . . £100 p.a. Fees 3/6 to 21/-. Purchaser, l . . . h Vendor. Good sport and schools. Premium 2 years' purchase.
17. SOUTH CORNWALL.—Near Sea.—Well-established PRACTICE producing about £700 p.a., including panel of over 600. Fees 5/- to 21/-. Suitable house, with 3 reception, 5 bedrooms, etc. Rent on lease £50 p.a. Good sport and mild climate. Premium 1½ years' purchase. Ill-health reason of sale.
18. WEST MIDLANDS.—Easily worked PRACTICE in residential village within easy reach of two good towns, and having very pretty surrounding country. Receipts average over £1,000 p.a., including panel of 500 and an appt. worth £150. Nice house with good garden and land of about 2 acres. Price for freehold £1,600. Fishing, hunting, etc. Premium 1½ years' purchase.
19. SURREY.—Increasing residential district, with good train service to town.—Well-established good general PRACTICE, offering Surgical scope. Gross cash receipts for last 12 months nearly £3,200, with panel of about 900. Visits 5/- to 21/-. Suitable house, with 3 reception, 7 bedrooms, etc. Can be bought or rented on lease. Premium 1½ years' purchase.
20. YORKS.—LARGE TOWN.—Old-established chiefly good working-class PRACTICE averaging about £1,300 p.a., including panel of 1,400. Fees from 2/6. Suitable house, with 3 reception, 4 bedrooms, and dressing room, etc. Garden; garage. Price £1,200. Premium 1½ years' purchase, chiefly by instalments.
21. NEAR HEREFORDSHIRE BORDER.—A one-third to one-half share in a well-established good-class non-dispensing PRACTICE, producing about £1,800 p.a. Panel of over 500. Good house can be rented at £60 p.a. Sport of all kinds. Premium 1½ years' purchase, part by instalments. Welsh not necessary.
22. SOUTH-WEST OF ENGLAND.—Near the Sea.—Old-established unopposed and easily worked Country PRACTICE, in beautiful district, within easy reach of Market Town. Receipts just under £1,100 p.a., including appts. and panel £550. Exceptionally attractive house in three acres of ground, with ample accommodation. Water laid on and electric light available shortly. Price freehold £2,600, part on mortgage. Premium £1,600. Sport and schools within reach.
23. YORKS. — HOSPITAL TOWN. — Old-established sound middle and working-class PRACTICE, producing about £1,300 p.a., including panel of 1,300, and appts. worth £50. Fees from 3/6. Small house with one reception, 3 bedrooms, boxroom, etc. Premium 1 to 1½ yrs.' purchase, payable by arrangement. Ill-health reason for sale.
24. CORNWALL.—VILLAGE PRACTICE, within easy reach of Plymouth.—PARTNERSHIP.—A one-half share in a very old-established mixed-class Practice, averaging £3,563 p.a., including panel of 850. Fees 3/6 to 21/-. Not much midwifery. Good house, with 3 reception, 6 bedrooms, etc. Large garden. Price for freehold £2,000. Sport of all kinds. Premium 1½ years' purchase.
25. NORTH LINCS.—COAST TOWN.—Old-established PRACTICE, producing last year nearly £2,900 p.a., including panel of 1,700. Fees 3/6 to 21/-. Practically unopposed. Good modern house, with special professional rooms. Nice garden. Garage. Freehold for sale, part on mortgage. Good sport and schools within reach. Premium 1½ years' purchase.
26. NORTH OF ENGLAND.—GOOD TOWN.—A one-third share is offered in a very sound PRACTICE averaging about £5,000 p.a. Ingoing partner must be well qualified, not over 35, and interested in medicine. Suitable house available. Premium 2 years' purchase.
27. WITHIN 20 MILES OF LONDON.—Old-established mixed-class PRACTICE, in small town amidst beautiful surroundings. Cash receipts average about £1,700 p.a., including appt. £70 and panel of over 1,000. Good house, with ample accommodation. Small garden. Price, freehold, £2,500. Premium 1½ years' purchase. Good educational facilities and sport of all kinds.
28. NORTH MIDLANDS.—Within 10 miles of County Town.—Very old-established good mixed-class PRACTICE, in pleasant village. Steady average income of £1,157, including panel of 759. Fees from 3/-. Not much midwifery at from 2 gns. Suitable house, with 2 reception, 6 bedrooms, consulting and waiting rooms. Electric light. Small garden. Rent on lease £51 p.a. Sport of all kinds. Premium 1½ years' purchase.
29. HOME COUNTY.—Unopposed Country PRACTICE, producing about £500 to £600 p.a., including panel of 650. Small house on main road, with 2 reception, 3 bedrooms, etc., and professional rooms. Rent on lease £52 p.a. Good sport and schools within reach. Low premium for quick sale.
30. CHESHIRE.—COAST TOWN, within reach of Liverpool.—Well-established PRACTICE averaging over £1,200 p.a., including panel of 780. Fees from 3/6. Mid. 2 to 5 gns. Double-fronted house, with 3 reception, 4 bedrooms, etc. Price for freehold £1,200, £800 on mortgage. Premium £1,100 for quick sale.

Full Schedule of Terms and Conditions will be forwarded on application.

Peptalac REGD.

THE NEW INSTANT PREDIGESTED FOOD

SIX OUTSTANDING ADVANTAGES

1 PEPTALAC is "made in a minute" by the simple addition of hot water giving in an instant a digested milk food of high digestibility.

2 PEPTALAC is fool-proof and requires neither technique, skill nor addition of milk. It renders obsolete the method of peptonisation wherein milk had to be held at a temperature 117°F. for 20-30 minutes under carefully controlled conditions.

3 PEPTALAC is guaranteed to have been pancreatised and the essential components of starch and milk proteins broken down to sugars, peptones, and amino-acids. With other methods of peptonisation this cleavage is uncertain and unreliable and the milk which is added is not predigested.

4 PEPTALAC is a safe and practically sterile powder. In the old methods of peptonisation, the milk was predigested at a temperature which is also favourable to the growth of organisms, thus resulting in a final product teeming with bacteria. Reconstituted PEPTALAC is free from pathogenic organisms and practically sterile.

5 PEPTALAC is therefore invaluable for infants, young children, the aged, convalescents, and the weak in health, who are prone to contract milk-borne diseases from ordinary milk or preparations made with it.

6 PEPTALAC is pleasing to the most fastidious palates—salt or chocolate may be added for further flavouring if desired.

THE LANCET.—"*A reference book used and valued by medical men in every part of the Empire.*"

Bristol: JOHN WRIGHT & SONS LTD. London: SIMPKIN MARSHALL LTD.

RECENTLY PUBLISHED. FIFTH EDITION. Fully Revised and Enlarged. Crown 8vo 1,048 pp. 21s. net; postage 9d.

SYNOPSIS OF
MEDICINE
By H. LETHEBY TIDY, M.A., M.D.,
B.Ch.Oxon., F.R.C.P.Lond.,
Physician, St. Thomas's Hospital; Consulting Physician, Royal Northern Hospital.

"An admirable *index medicus*. . . . The scope is far wider than in the majority of books. Throughout, 'treatment' meets with ample consideration . . . this fact alone will enhance its value enormously for the busy practitioner."—BRIT. MED. JOURN.
"We can say without hesitation that the book is far ahead of any medical synopsis it has been our lot to encounter."—LANCET.
"We have nothing but admiration for this book, and cannot commend it too highly."—MEDICAL PRESS AND CIRCULAR.

NINTH EDITION. Fully Revised. Crown 8vo. 684 pp. With 165 Illustrations, some of which are coloured. 17s. 6d. net; postage 9d.

SYNOPSIS OF
SURGERY
By ERNEST W. HEY GROVES, M.S., M.D.,
B.Sc.Lond., F.R.C.S.Eng.,
Professor of Surgery, Univ. of Bristol; Surgeon, Bristol General Hospital; Member of the Court of Examiners, Royal College of Surgeons, England; Examiner in Surgery, Universities of London, Liverpool, Leeds, Manchester and Sheffield, and Nat. Univ. of Ireland.

"Complete in its range of subjects . . . among the best of its kind; the author is to be congratulated on its readableness, its lucidity and its fullness—notable qualities."—BRIT. MED. JOURN.
"This synopsis of surgery has had a wide sale, which has necessitated the issue of frequent editions, and it deserves thoroughly all the success it has attained."—LANCET.

Bristol: JOHN WRIGHT & SONS Ltd. [Illustrated Catalogue free.] London: SIMPKIN MARSHALL Ltd.

HEALTH AND SOCIAL EVOLUTION
By Sir GEORGE NEWMAN, K.C.B., M.D., F.R.C.P. *Halley Stewart Lecture, 1930* 4s. 6d.

Sir George Newman traces the progress which has been made in combating disease in England, and outlines the work to be done in future and the principles and methods to be followed.
"Most interesting and informative."—*Daily Mail.*

LONDON: J. & A. CHURCHILL, 40, Gloucester Place, Portman Square, W.1

SPORTS WEAR

TERMS FROM £1 MONTHLY

● West End clothing invariably creates a feeling of confidence which tends to improve one's game. Unfortunately many people fail to appreciate this fact, judging by the way old clothes seem to survive relegation. . . . This is not easy to understand, especially as Keith Bradbury makes a point of supplying, for all occasions, clothing cut to give you the neatness of a new suit with the comfort of the old—AND £1 PER MONTH IS ALL YOU NEED PAY. . . . Then there is the Free Valeting Service for sponging, pressing and repairing, as often as you wish, to keep your clothes always clean and neat. . . . References or enquiries, of course, are entirely unnecessary and we have a little book explaining our methods. . . . May we send you a copy with patterns?

Sports wear and lounge suits from 5 gns. Flannel trousers from 21/-. Flannel blazers from 45/-. Dinner and evening wear from 6 gns.

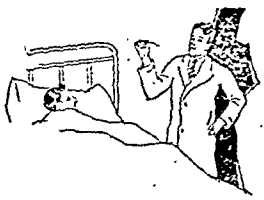
WHICH EXISTS TO PROTECT YOUR INTERESTS AND SAVE YOUR MONEY.



You're always taking temperatures . . .

but do you ever take the temperature of your own Larder?

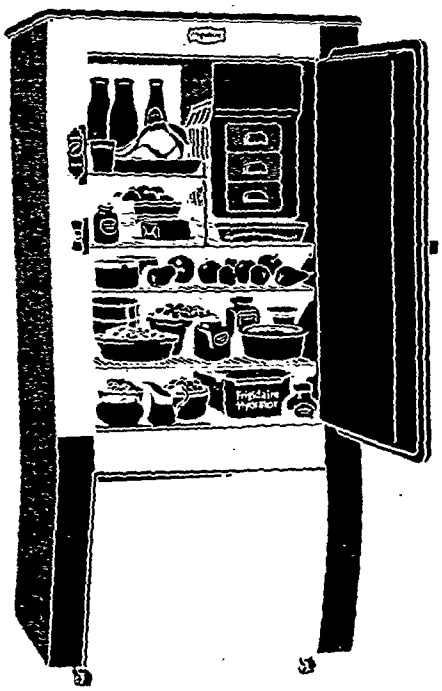
JUST try the experiment. Remember that over 50° for your food is *just* as bad as over 100° for your patient. Over 50°, bacteria multiply in food 400 times faster than at temperatures below. And, apart from the health reasons, wouldn't it be comforting to know that your food was kept cold and appetising and fresh, in a snow-white all-porcelain Frigidaire, shut away from the dirt and flies, *automatically* prevented from "going off"? Perhaps you've been promising yourself a Frigidaire—then send in the coupon to-night and see how little it costs!

Frigidaire incorporates all the conveniences and refinements that you would wish to have in your electric Refrigerator. Here are just a few of them.

The Quickube Ice Tray, enabling single cubes, or many, or all, to be extracted at once, simply by a light pressure of the finger. No melting them out under the tap. Your cocktail ice is ready at a moment's *notice*. This is an exclusive Frigidaire feature.

The Cold Control, by which the freezing of ice cubes or any frozen delicacy can be accelerated at will.

The automatic feature of Frigidaire is invaluable. It cuts out the human element with its forgetfulness and consequent waste. Frigidaire maintains a dry cold that is *always* under 50°—the only safe temperature for food.



Practical flat top, makes a useful shelf.

The Hydrator—a *moist* cold compartment, for fresh vegetables, sandwiches, *etc.* Even wilted vegetables will regain their crispness here in a few hours.

Ease of installation. A Frigidaire only needs connection with your electric supply. *No plumbing is necessary.*

The new Frigidaire is quiet—you can't hear it start, stop or run.

Showrooms at 141, New Bond Street, London, W.1, and in all principal towns.

Since Aneroid Gauges depend for their action on the stretching, under pressure, of metal diaphragms, they are subject to the usual errors arising from the elastic properties of metals.

The Lifetime Baumanometer, on the other hand, operates on the immutable law of gravitation—and does not depend for its action on the material used in construction.

Portability, the only excuse in the past for using aneroid instruments, of doubtful accuracy, is now equally obtainable in the Lifetime Baumanometer.

Moreover, all Lifetime Baumanometers are individually calibrated, scientifically accurate, and guaranteed to remain so. Everyone is a MASTER instrument and carries our exclusive guarantee against glass breakage.

The Lifetime Baumanometer's distinguishing specifications, have won for it the approval of more than one hundred thousand doctors the world over.

Among the many models to choose from, is the New Kompak Model—the smallest, lightest, handiest, mercurial instrument.

Your surgical instrument dealer will gladly demonstrate it or send one to you.

MICKLEFIELD IRRADIATED MILK

TREATING THE COW

By this Process—

(1) VITAMIN A AND NATURAL FLAVOUR ARE PRESERVED.
(2) VITAMIN D CONTENT IS INCREASED 1,800 PER CENT., OR TEN TIMES THAT OF ANY OTHER IRRADIATED MILK.

One pint equivalent in Vitamin D to 600 drops or 12 grammes of average Cod-Liver Oil.

A ten weeks' test recently conducted at the Infants' School, Rickmansworth, under the supervision of the Medical Officer of Health, gave the following results:—

(1) 18 children (controls) had their usual ordinary milk.
(2) 29 " 1/3-pint of Grade A (T.T.) milk five days a week.
(3) 30 " " Micklefield " " "

(1) Average increase in height '605-in. (2) Average increase in weight 9·72 ozs. more than (1).
(2) " " " '610-in. (3) " " " 10·9 ozs. more than (1).
(3) " " " '744-in.

Full particulars appeared in an article in the LANCET, January 18, 1930, p. 127, et seq., a reprint of which will be sent post free on request.

The milk is delivered every week-day in London; elsewhere by arrangement.

Write to J. O. HICKMAN, MICKLEFIELD GREEN, RICKMANSWORTH.

REGULOL

REGD.

"REGULOL" IS AVAILABLE IN TWO FORMS: "PLAIN" or "COMPOUND." The latter is a combination with Phenolphthalein 4 grains per oz., and is indicated in more acute forms of Constipation where the simple lubricating effect of Paraffin is insufficient.

CUXSON, GERRARD & Co., Ltd.
Oldbury, *Birmingham.*

IT is a highly palatable Emulsion of Liquid Paraffin with Agar-Agar, possessing all the advantages of the former without its objectionable qualities, and forming probably the best possible remedy for Chronic Constipation in Children and Adults.

SAMPLE 1-lb. JAR FREE ON REQUEST.

Please indicate whether Plain or Compound is required.

(This offer is limited to the British Isles.)

ALIMENTARY TOXÆMIAS

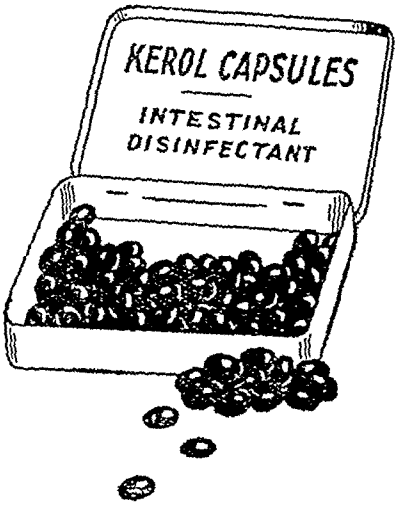
IN our last advertisement, the subject of Alimentary Toxæmia was briefly discussed, and intestinal disinfection by means of Kerol Capsules was held to be the first line of treatment.

The reason for this may be stated as follows:—None of the ordinary so-called intestinal antiseptics, such as Salol and Beta Naphthol, are found experimentally to exert any disinfection of the contents of the bowel.

On the other hand, the high boiling hydroxyl compounds of the coal tar series are potent germicides, and, being unabsorbed, are non-toxic. They can therefore be administered freely without harm, and are found to prevent the multiplication of the toxæmic intestinal bacteria and to reduce them considerably.

The active principle of Kerol is a complex mixture of these compounds. The administration of two 3-minim capsules thrice daily after meals has been repeatedly shown to reduce the coli content of the stools of individuals taking them by 99 per cent.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.



Kerol Capsules

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

DOCTOR'S CHINA TEA

FOR ALL CASES OF GASTRIC TROUBLE.

It is definitely not safe to allow any tea but China tea to be used when there is the slightest tendency to gastric trouble. The Doctor's China Tea has no excess of Tannin whatever—it is a really good blend of China tea—it is therefore ideal as a delicious and healthful drink for all who enjoy a good cup of tea and especially for those of your patients who suffer from any form of indigestion.

HARDEN BROS. & LINDSAY, LTD.
(Dept. 153), 39/34, Mincing Lane, London, E.C.3.

IT IS THE DIFFICULT CASES OF INFANT FEEDING WHICH PROVE THE WORTH OF HUMANISED TRUFOOD

Humanised Trufood so closely resembles breast milk that independent investigators claim that there is hardly any difference between the two. This close proximity to Nature's provision is the reason why the most backward infants make progress on it—from the first feed!

THESE ESSENCES POSSESS THE THREE THINGS WANTED IN AN INVALID FOOD

they stimulate . . .

they rouse appetite . . .

they make no strain on the digestive system

BY APPOINTMENT

AT the critical time when patients are unable to digest solid food, Brand's Essences of Beef or Chicken stimulate and supply energy without strain to the digestive system.

Recent scientific tests have shown that Brand's Essences are assimilated by the digestive organs forty minutes quicker than ordinary food and without the formation of residue.

Suave and non-irritating, they are particularly suitable in all cases of intestinal disturbances, in disorders associated with pyrexia, and before and after operations.

Brand's Essences of Beef or Chicken, hygienically prepared by an exclusive process from the finest freshly killed English meats, consist of the pure essence of meat expressed in its natural form—a clear, appetizing jelly, delicious and easy to swallow.

Write in for samples to-day. They will be gladly sent on receipt of a professional card, Dept. F32, Brand & Co. Ltd., Mayfair Works, South Lambeth Road, London, S.W.8.

BRAND'S ESSENCES OF BEEF OR CHICKEN

The Treatment of

Pernicious Anaemia

The physician prescribes liver as a matter of routine in pernicious anaemia and in other anaemias which resemble the pernicious type in that they appear to be associated with megaloblastic hyperplasia of the bone marrow.

Cases occur, however, which do not appear to derive continued benefit from liver, but which respond more satisfactorily to treatment with desiccated stomach.

The needs of all cases of the pernicious type are met, therefore, by the employment of the two British products described below.

LIVER EXTRACT B.D.H.

Liver Extract B.D.H. is a freely-running powder; it is made by a process tested and found efficient by The Medical Research Council, each tube containing the haematopoietic principles of half-a-pound of fresh raw liver.

GASTER SICCATA B.D.H.

Gaster Siccata B.D.H. is a fine light powder, odourless, practically fat-free and resembling in taste an ordinary milk food diet; it is made from fresh stomachs obtained in Great Britain from certified healthy animals.

The Medical Profession when prescribing "Liquor Carbonis Detergens" SHOULD ADD THE WORD

Wright's

On receipt of your professional card, a package will be sent containing a sample of each of the following—

Wright's Coal Tar Soap.
Wright's Coal Tar Ointment.
Wright's Lysol.
Wright's Liquor Carbonis Detergens.

Although there is no secrecy as to the composition of Liquor Carbonis Detergens (it is described as "an alcoholic solution of coal tar"), the method of manufacture is unique. Imitations will be found to be produced by simple digestion, usually accompanied by some primitive, perfunctory, and inadequate stirring; whereas, in the case of the genuine product, the intimate contact required, for the complete extraction of all the soluble antiseptic constituents, is attained by a series of complicated processes, involving the use of highly specialized machinery.

HORLICK'S MALTED MILK has for many years been advocated as an excellent addition to the diet of the nursing mother, for whom correct dieting should be a matter of the greatest importance. It has been well said that the mother's milk is the baby's birthright. In the early months of life the foundation of baby's future health is laid, and among the many factors which go to the building of this foundation the quality and quantity of the mother's milk are of vital importance. Should the mother's dietary be deficient in any of the important food constituents, her own health and the quality of her milk will be adversely affected and baby will ultimately suffer in consequence. HORLICK'S MALTED MILK, made from full-cream cow's milk and the nutritive extracts of malted barley and wheat, contains all the food elements that the nursing mother needs. It is a well-balanced food, which invigorates and energizes. It stimulates mammary secretion, and ensures that baby's food requirements are adequately fulfilled; it makes the nursing period a joy, and not a time of worry and anxiety.

CAPROKOL

Brand of Hexyl-Resorcinol

The remarkable value of Caprokol in the treatment of urinary tract infections is consequent, to a considerable extent, on its power to reduce the surface tension of the urine, thus rendering it highly penetrative.

Low Surface Tension

Caprokol administration therefore results not only in the transformation of the urine into a highly bactericidal solution, but it also ensures that this disinfecting and purifying stream permeates into all the interstices of the urinary tract, rendering it eventually completely sterile.

High Penetrative Power

Furthermore, Caprokol possesses a gentle analgesic action that brings immediate ease and comfort—which condition, together with the fact that Caprokol does not stain, is appreciated by the patient.

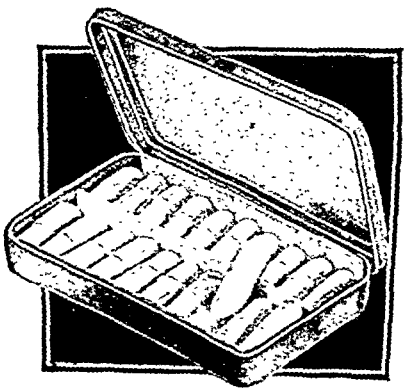
A *New* chemo-therapeutical preparation
for the treatment of influenza, septic diseases and toxemias



Used in America for treating Influenza for the past two or three years with great success. The physician's sample illustrated here will be sent to you free on request.

Indications.
Influenza Colds, Pyelitis, Puerperal Sepsis, Surgical Sepsis, Bronchial Asthma, Obstetric Morbidity, Cystitis, etc.

DISULPHAMIN is a mixture of Sulpho-salicyl formol sodium nucleinate and Dimethylamino-antipyrin combined with camphor. The antitoxic action is based on the assumption that Disulphamin transforms the toxic colloid to a crystalloid, thereby facilitating its dialysis through the walls of the blood vessels, and accelerating its elimination by the kidneys.

While phenol is bactericidal in a 1/100 dilution, Disulphamin is bactericidal in a dilution of 1/10,000 to 1/50,000.

In a series of tests made in the treatment of Influenza with Disulphamin, it was found that the course of the disease was materially shortened, and very seldom did Broncho-pneumonia or other complications supervene. Although the etiology of influenza has not yet been clearly determined, it appears that Disulphamin exerts a polyvalent action.

The clinical results thus far obtained are so encouraging that physicians have ample justification for employing Disulphamin in Febrile Toxemias arising from Sepsis.

Samples and literature, including charts of actual tests and important hospital findings, will be sent free on request to Messrs. COATES & COOPER, 41, Great Tower Street, London, E.C.3.

DISULPHAMIN

Product of
THE BIO-CHEMICAL LABORATORIES
LOCARNO, SWITZERLAND

A safe and simple antacid which is also a gentle laxative must necessarily be of great value to medical practitioners when administering to ladies and children and all who are constitutionally delicate.
May we, therefore, venture to remind you of

DINNEFORD'S PURE FLUID MAGNESIA

which has been extensively prescribed and used by the Medical Profession for a Century, and is still the best and safest means of administering Magnesia.

When prescribed for the nursery, too, Dinneford's Magnesia has always proved immensely useful as a corrective, and when mixed with infant's food it prevents many of the troubles which are due to acidity, flatulence, etc.

We are confident that you will find in Dinneford's Fluid Magnesia a reliable and safe solution which may be freely used for many ailments, and we would request your kind consideration of its use as occasion offers.

Dinneford's Pure Fluid Magnesia possesses antacid and laxative qualities which are incomparably better than those of any of the various preparations of Magnesia, in powder, now being introduced.
It cannot harm the most delicate constitution and is at all times a safe and effective laxative.
Manufactured in London for the past 100 years.

DINNEFORD & Co. LTD.

STANIFORM

Regd. BRAND. Trade Mark.

METHYL STANNIC IODIDE

OINTMENT
Immediately stops the pain in all cases of burns, scalds, etc.

DUSTING POWDER
For application where a greasy substance is contra-indicated.

LINIMENT
Remarkably effective in treatment of Rheumatoid Arthritis.

LOTION
A anacea for Mosquito and other insect bites. Most effective for all purposes where Tr. Iodine is employed. Does not stain the skin and there is no sting.

TABLETS
Staniform being an organic compound is more easily assimilated than the Tin preparations at present in use.

Supplies may be obtained through the Wholesale Druggists, Druggists' Sundriesmen, or Dental Supply Companies.

What the Profession says

The following are some recent unsolicited testimonials reported to the Manufacturers by Medical Men:

"*I have treated with 'Staniform' a very bad scald of chest in a child, who had boiling water spilt over her. It healed completely in fourteen days without a scar.*"

"I have tried 'Staniform' in the Out-patients' Department and both Nursing Staff and myself were amazed at results obtained. Long-standing, non-healing skin wounds healed after few applications."

"This is to certify that 'Staniform' has been used with great success in the Emma-Klinick (Utrecht, Holland), in cases of bed-sores, in burns of heat and X-rays."

Similar testimony has been received from a large number of medical men when "Staniform" has been used for the treatment of Burns, Wounds, and Skin Ailments

STANIFORM is used in Leading Hospitals.

STANIFORM over a wide field of clinical experience has exhibited positive curative properties. Combining the well-known usefulness of Tin in staphylococcic infections with the powerful germicidal properties of Iodine, Staniform is indicated generally in local inflammations, inducing an immediate soothing effect with rapid healing.

STANIFORM LTD., CARNWATH ROAD, LONDON, S.W.6

ALOCOL

Colloidal Hydroxide of Aluminium

THE increasing prevalence of gastric ulcer and hyperchlorhydria has produced an advance in the treatment of these diseases.

"Alocol" (Colloidal Hydroxide of Aluminium) provides an antacid medicament far superior to subnitrate of bismuth, bicarbonate of soda and other alkalis. These merely afford a certain degree of ease, without bringing about a permanent relief of the condition.

"Alocol" absorbs the excess of hydrochloric acid without interfering with the normal antiputrefactive function of the gastric juice or harmfully affecting the processes of nutrition.

"Alocol" has been subject to extensive clinical trial, and literature giving full particulars of the results will be gladly sent to medical men on request.

For Acute or Chronic Cases of Hyperacidity

For Gastric Duodenal or Pyloric Ulcers

M.232.

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl-salicylic acid possesses a notable disadvantage. Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach. Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced.

"Alasil" completely overcomes this objection. By combining calcium acetyl-salicylate with "Alocol," unfavourable secondary action upon the stomach is prevented. This beneficial influence is undoubtedly due to the presence of "Alocol" (Colloidal Hydroxide of Aluminium), which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract. "Alasil" is therefore a triumph over acetyl-salicylic acid. It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time. Analgesic, Antipyretic, and Sedative, "Alasil" is indicated in all cases where acetyl-salicylic acid has been used heretofore.

A supply for clinical trial with full descriptive literature sent free on request.

BETTER MILK FOR BABIES

FACTS ABOUT
LACTOGEN

Carbohydrates

Compared with maternal milk the carbohydrate content of cows' milk is considerably deficient, but in Lactogen—by suitable modification—this deficiency has been rectified.

Unlike ordinary dried milks, in which the carbohydrate is in the same proportion as in the raw milk, LACTOGEN CONTAINS PRACTICALLY THE SAME AMOUNT OF CARBOHYDRATE AS WOULD BE FURNISHED BY HUMAN MILK.

Lactogen is neither a new nor untried product. First introduced in Australia, it has for many years enjoyed a large sale in overseas countries.

"LACTOGEN"
REG. TRADE MARK

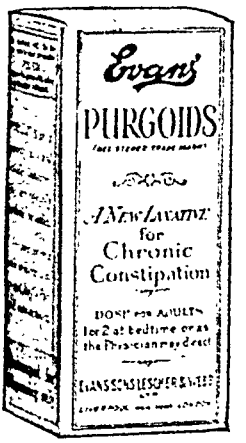
BETTER MILK FOR BABIES

FREE SAMPLES with detailed descriptive literature will be sent to any Member of the Medical Profession, upon request. Lactogen Bureau (Dept Z6), Nestlé and Anglo-Swiss Condensed Milk Co., 6 & 8, Eastcheap, London, E.C.3.

(Aesculapius)

PURGOIDS

Purgoids present a most effective combination of Phenolphthalein, Aloin, Ipecac, Belladonna, etc., in sugar-coated tablet form. They are of great value in cases of constipation, acting without depression action. Peristalsis is promoted without griping and intestinal secretion is increased.



In long-standing cases of chronic constipation it has been noted that patients have fully recovered, and have not found any further laxative necessary. Purgoids have been found to be of special value to nursing mothers, as they do not affect the baby.

Issued in bottles of
25, 100, 500, and 1,000.

A Physician's sample will be sent with pleasure, on request.

MILK POWDER for SAFETY!

Extract from the Annual Report for 1928 of the Medical Officer of Health for———

INFANTILE DIARRHŒA

"Until the methods of farmers and others concerned in the milk industry have been revolutionised, and consumers have been provided with facilities for storage and education in the handling of milk, *I am definitely of the opinion that liquid milk should be banished from the dietary of infants.*"

Many such extracts show that the opinion of the Medical profession is rapidly turning to the use of specially prepared Milk Foods in infant feeding as the only safe and suitable substitute for breast milk.

Cow & Gate Milk Food

The best milk for babies, when natural feeding fails.

The following extracts from *The Lancet*, and the Presidential Address at the Royal Sanitary Institute Congress at Margate, show the risk run in feeding raw milk to infants:

'There can therefore be no doubt that a fair proportion of cases of ordinary adult phthisis in Scotland are due to the bovine bacillus .....'—*The Lancet*

....'But when to this is added the fact that in England 31.5 per cent. of tuberculosis in children up to 15 years of age is of bovine origin, and deaths from tuberculosis in children up to 5 years is 29.5 per cent. of bovine origin, that 57 per cent. of cervical adenitis in the same ages is of bovine origin, that 33 per cent. of bone and joint tuberculosis in children under 5 years and 24 per cent. in children from 5 to 10 years is of bovine origin, that in Scotland it is recorded that in certain hospitals in Edinburgh as much as 90.3 per cent. of cervical adenitis and 61.2 per cent. of bone and joint tuberculosis in children up to 12 years is of bovine origin, it is high time that this grave condition and this very serious menace to public health should be mended and ended.'

Extract from Presidential Address, Royal Sanitary Institute Congress, Margate.

COW & GATE MILK FOOD

is prepared by our Special Improved Roller Process employing a short heat treatment which destroys all disease organisms but leaves the natural vitamins and minerals unimpaired. *It is a basic milk food which can be modified by the professions as they desire to suit all and every case.*

The Superiority of Cod Liver Oil as a Cure for Rickets

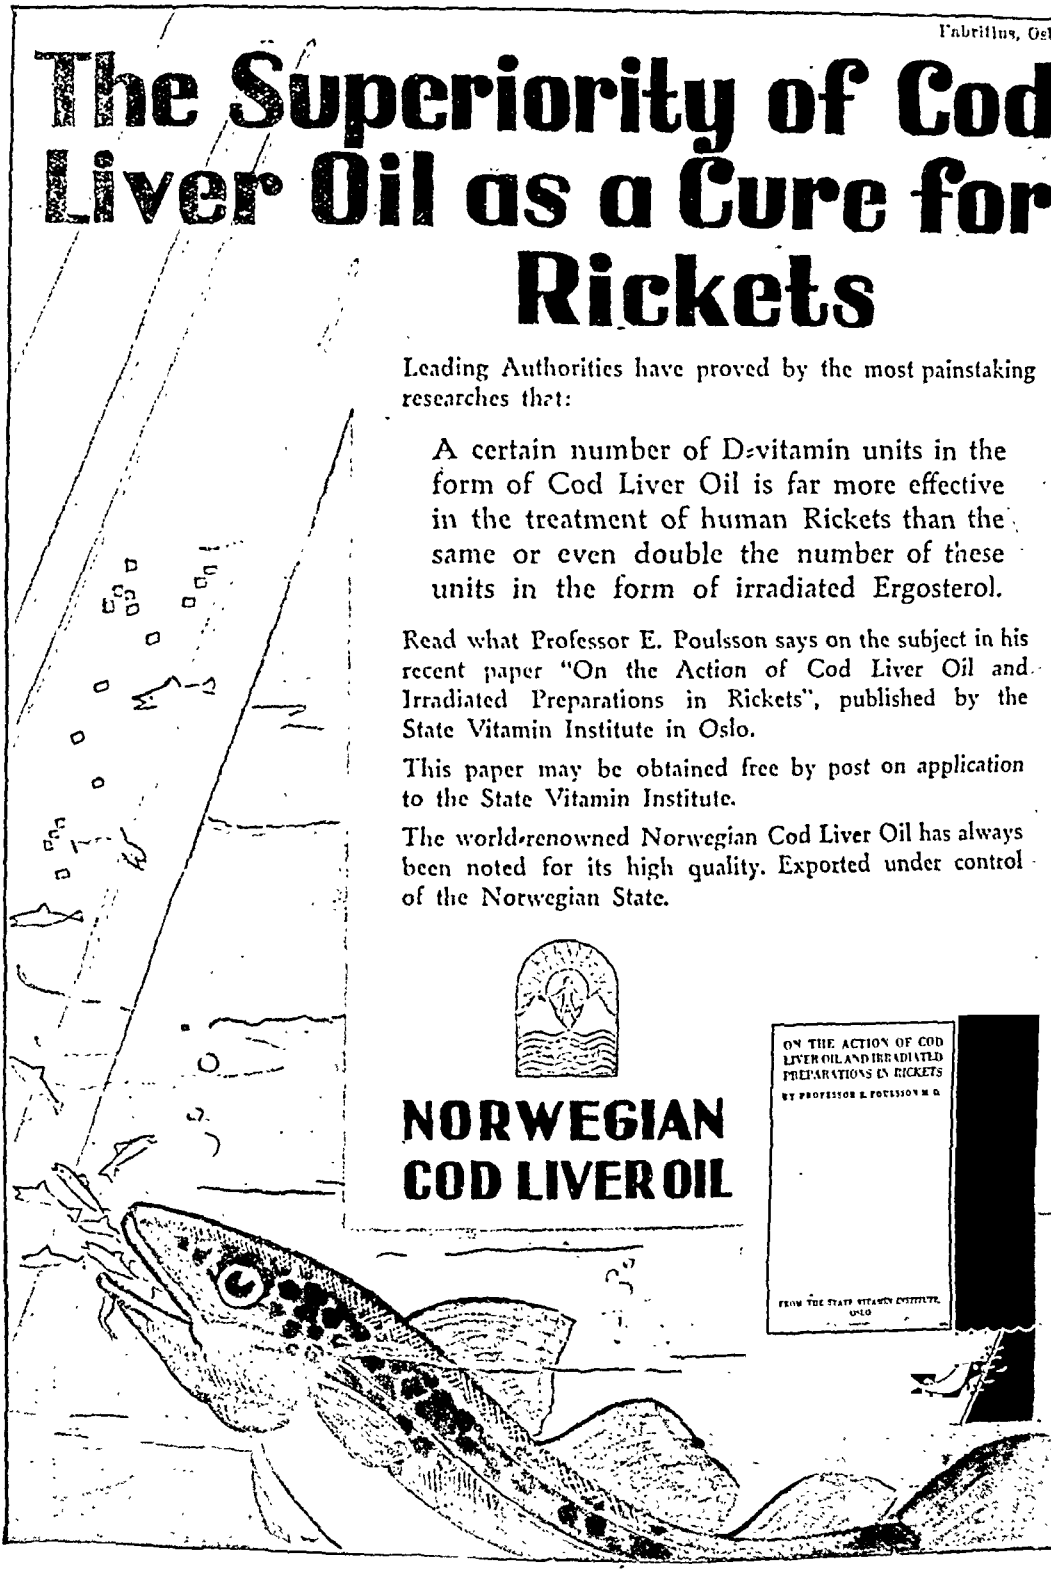
Leading Authorities have proved by the most painstaking researches that:

A certain number of D-vitamin units in the form of Cod Liver Oil is far more effective in the treatment of human Rickets than the same or even double the number of these units in the form of irradiated Ergosterol.

Read what Professor E. Poulsson says on the subject in his recent paper "On the Action of Cod Liver Oil and Irradiated Preparations in Rickets", published by the State Vitamin Institute in Oslo.

This paper may be obtained free by post on application to the State Vitamin Institute.

The world-renowned Norwegian Cod Liver Oil has always been noted for its high quality. Exported under control of the Norwegian State.



NORWEGIAN COD LIVER OIL

CREMOR ALKALINUS 'A.&H.'

For the Intensive Alkaline Treatment of Gastric and Duodenal Ulcers

Formula A

Sod. Bicarb.	2 parts
Mag. Carb.	4 parts
Calcium Carb.	4 parts
Bismuth Carb.	1 part

This is the standard preparation.

Formula B

Sod. Bicarb.	2 parts
Mag. Carb.	3 parts
Calcium Carb.	4 parts
Bismuth Carb.	2 parts

This is employed in cases where Formula A proves too laxative.

Formula C

Sod. Bicarb.	3 parts
Mag. Carb.	6 parts
Calcium Carb.	12 parts

Specially suitable for cases in which a bismuth-free preparation is desired.

For the convenience of practitioners the approved formulæ are prepared in the form of simple creams which are exceptionally free from grittiness.

In 8 oz. bottles for prescribing.

In 80 oz. bottles for dispensing.

Descriptive booklet and clinical trial sample sent post free on application.

Formula D

Mag. Carb.	4 parts
Calcium Carb.	6 parts
Bismuth Carb.	1 part

For cases where the use of Sodium Bicarbonate is regarded as disadvantageous.

Formula K

Sod. Bicarb.	2 parts
Mag. Carb.	3 parts
Calcium Carb.	4 parts
'Osmo' Kaolin	2 parts

The bismuth is replaced by colloidal kaolin which possesses marked toxin-adsorbing properties.

Cremor Alkalinus "A. & H." Lozenges

Prepared from Formula C. Convenient for carrying in the pocket. Each lozenge contains 15 grains.

THE RATIONALE OF THE ACTION OF RYVITA CRISPBREAD IN CERTAIN SPECIAL CONDITIONS

CONSTIPATION

The use of Ryvita Crispbread as a corrective where constipation exists is advocated by an increasing number of the Medical Profession.

The special laxative properties of rye grain are well known. Ryvita is made of pure, whole-grain rye, crushed, which is rich in vitamin B, and the salts of lime and iron and phytates.

The ready digestibility of Ryvita, and the low percentage in it of unconverted starch, ensures against starch fermentation, thus keeping the whole alimentary tract in wholesome condition. The roughage and mineral salts of the bran ensure daily natural evacuation of the bowels.

An Eminent Authority declares:

"Washed wheat bran fed to cows was found to be constipating, indicating that the laxative property of ordinary bran and whole-grain products is dependent not simply upon mechanical irritation, but largely, if not mainly, upon the phytates."

It is not improbable that the vitamin B content of Ryvita has also a stimulative effect upon intestinal movements. Reports of recent dietetic research tend to confirm this view.

Many Doctors testify that Ryvita Crispbread gives excellent results in combating habitual constipation. Ryvita is definitely indicated as an item of the dietary in the treatment of disorders arising from indigestion, constipation, or malnutrition. It is usual to suggest that the patient begin by eating two or three slices of Ryvita with at least one meal each day.

RYVITA

CRISPBREAD

We shall be very pleased to send Free Samples and full particulars to any interested Member of the Profession.

A Paper ON ULCERATIVE COLITIS*

BY

ARTHUR F. HURST, M.D., F.R.C.P.

SENIOR PHYSICIAN TO GUY'S HOSPITAL

Sir Samuel Wilks, who in 1875 was the first to describe ulcerative colitis, pointed out that the condition was anatomically indistinguishable from dysentery. During the war I had frequent opportunities, at Lemnos and at Salonica, of sigmoidoscoping patients with dysentery. I recognized at once that amoebic dysentery presented a characteristic picture which bore no resemblance to that of bacillary dysentery, and that it was impossible to distinguish the latter from the ulcerative colitis with which I was already familiar.

NATURE OF THE DISEASE

That infection with *B. dysenteriae* occurred in England was already well known from Eyre's investigations in 1894 on asylum dysentery. In 1912 Nabarro isolated the dysentery bacillus from a child who had been attending the Great Ormond Street Hospital for many years as a case of recurrent colitis. Since then he has found that not only many cases of summer diarrhoea, but many in small children diagnosed as chronic colitis, are caused by the dysentery bacillus. It is easy to understand how adults occasionally become infected with ulcerative colitis, due to *B. dysenteriae*, from children with these conditions, and yet do not themselves start a house epidemic, just as all the cases of amoebic dysentery arising in England which I have seen have been isolated ones. In 1923 Dudgeon isolated Flexner's bacillus in two cases of ulcerative colitis from material obtained from the surface of an ulcer examined through a sigmoidoscope. In 1927 Hadfield obtained it from the swab from an ulcer in a case I sigmoidoscoped forty-eight hours after the onset of haemorrhagic diarrhoea. The bacillus was isolated by Thorlakson and Cadman of Winnipeg in 1928, in six out of nine cases, from material obtained by scraping the base of an ulcer with a sharp curette, though they had never before discovered it in stools or in ordinary swabs from the ulcer surface. Last year Knott isolated Flexner's bacillus, which was agglutinated by the patient's serum, from a swab obtained from the raw surface left after I had snared a polypus in the rectum of a woman, aged 36, who had had very severe ulcerative colitis since 1925 and had developed two long strictures and multiple polyposis, although numerous examinations of stools and swabs taken from ulcers during the five years of her illness had only shown the usual organisms found in such cases.

It is well known that it is difficult to isolate the *B. dysenteriae* from the stools of patients in the Tropics suffering from typical dysentery after the acute stage has passed. The majority of cases of ulcerative colitis which come under skilled observation in England are already chronic, so that it can be easily understood how rarely the organism is found. In my only early case it was isolated without difficulty, and both Thorlakson's cases and the case I have just described show that it may be present in the depth of the lesion, when it cannot be demonstrated in stools or in swabs taken from the ulcers. These positive findings seem to me to be of more importance than many negative observations. The identical morbid anatomy and the response of many cases, especially early ones, to specific treatment with antidysenteric serum confirm the view which was first expressed by Saundby in 1906, and by Hawkins in 1909, and which I have consistently held since the war, that the disease is a form of bacillary dysentery.

Achlorhydria, which was generally secondary to gastritis, was present in about 25 per cent. of my cases. This is an important predisposing cause, as the absence of the normal acid antiseptic barrier of the stomach allows organisms swallowed in infected water or food to reach the intestines.

COMPLICATIONS

I have realized only in recent years the frequency of certain serious complications of ulcerative colitis, which were never recognized before the war. This is probably due to the fact that numerous severely affected persons who would formerly have died now survive as a result of better treatment; many recover completely, but in others the disease runs a very chronic course, which gives time for these complications to develop.

Among 693 cases at the Mayo Clinic between 1923 and 1928 there were 69 patients with adenomatous polyposis, 59 with stricture, 26 with perirectal abscess, 18 with perforation, and 15 with malignant disease, in addition to 30 with arthritis (Bargen). This agrees closely with my own experience of the relative frequency of these complications, except that I have never seen a case of perforation. Though the ragged polypoid tags of mucous membrane mentioned by Dr. Cuthbert Dukes are often mistaken for true polypi, there is no doubt that true polypi also occur; some of those I have removed have been found on microscopical examination to be typical adenomata, and their *x*-ray appearance is identical with that of primary polyposis. In a few such cases the polypi have completely disappeared with deep *x*-ray treatment; but this should never be used until the primary ulceration has healed. It is most important to remember that strictures may develop without any change in the symptoms; in chronic cases a barium enema should therefore be given from time to time. I have had three cases in which complete recovery followed a short-circuiting operation, without which death would certainly have occurred. One patient has now been well for six years. There was stasis in the enormously dilated caecum and terminal ileum for seven days, although she was still having the usual severe haemorrhagic diarrhoea. In another case with an eleven years' history the strictures were associated with polyposis. I have seen two cases in which carcinoma apparently developed from polypi of the rectum following ulcerative colitis, and in another, carcinoma, polyposis, and active ulceration were all present together. Anal infections are of great importance, as they may persist after the colitis has healed, and may lead to reinfection of the colon.

DIAGNOSIS

Direct examination of the mucous membrane of the rectum, which is almost always the part first affected and last to heal, is essential for diagnosis and for guidance in treatment. For those with limited experience a long proctoscope is easier to manipulate than a sigmoidoscope; it has the advantage of bringing the mucous membrane nearer to the eye, and the condition of the anal canal—a matter of considerable importance—can be more easily investigated. I have seen several cases of polypi and of carcinoma of the rectum and pelvic colon which had been treated as ulcerative colitis until I sigmoidoscoped them. I have recognized with the sigmoidoscope about half a dozen cases of amoebic dysentery in patients who had never been out of England and who, having hitherto failed to respond to treatment, recovered completely after twelve injections of emetine. I recently proctoscoped a patient who had been regarded as suffering from

*Read in the Proctological Section of the Royal Society of Medicine on March 11th.

long-standing ulcerative colitis. The mucous membrane of the rectum was normal, the blood having come from haemorrhoids, and the lumen was filled with effervescing fluid faeces, which indicated that the diarrhoea was due to carbohydrate intestinal dyspepsia. Rapid recovery followed abstention from starch-containing vegetables.

X-RAY INVESTIGATION

The *x* rays are very useful in investigating cases of ulcerative colitis. As the normal haustration of the bowel disappears in the affected part, it is possible, by means of a barium enema, to determine the extent of the disease. It is not uncommon for more or less of the proximal part to be spared in cases in which the pelvic colon and rectum are severely involved. When recovery takes place the haustration returns, except in very chronic cases. The proximal part of the colon is the last to be involved and the first to recover; the disease almost always begins and ends in the rectum and pelvic colon, so that sigmoidoscopy detects the earliest stage of the disease, and when the mucous membrane of the rectum and pelvic colon are found to be no longer inflamed it may be assumed that the same is true of the whole colon. A barium enema also reveals the presence of strictures, but it is possible to distinguish between those caused by prolonged spasm and those caused by organic disease only by means of an opaque meal. Narrowing due to spasm does not cause any stasis, the colon being evacuated with great rapidity, whereas that due to a fibrous stricture leads to severe stasis in the dilated proximal segment. Lastly, the presence and extent of multiple polypi can often be recognized after an opaque enema or meal.

TREATMENT

Rest in bed, warmth, and a generous mixed diet, from which the skins and pips of fruit and fibres of vegetables are alone excluded, are essential parts of treatment. When anaemia is present transfusion not only improves the general condition, but often greatly hastens the healing of the ulcers.

By absorbing gas, charcoal often makes the patient much more comfortable. Of the various drugs used locally I have found tannic acid (1 to 2 grains to 1 ounce) the most useful. If given after preliminary lavage with normal saline solution under low pressure through a soft catheter introduced just beyond the anus, it reaches the caecum, and is generally just as effective as if given through an appendix or caecal stoma. Quite recently I have been using dilute hydrogen peroxide (1 drachm to 1 pint) without preliminary lavage, and I am inclined to think this may prove even more satisfactory than tannic acid.

In the first case in which I used polyvalent anti-dysenteric serum in 1921, the result was little short of miraculous. A young man who was almost moribund after being very ill for over a year, and in whom no improvement had followed an appendicostomy, recovered completely in a fortnight; five days after the first injection the sigmoidoscope showed that the innumerable ulcers seen a few days before had vanished, and nine days later the appearance of the mucous membrane was absolutely normal. Since then I have had a number of cases in which a dramatic recovery has taken place, and my colleagues Dr. Fawcett and Dr. Ryle, and Jerwood, Bindon Brew, and many others, have had similar experiences. Rapid recovery is most likely to occur in early cases, but it is occasionally observed in those which are very chronic. Thus, complete recovery occurred within a week in the very early case I have already mentioned in which Flexner's bacillus was isolated. More frequently the serum produces a certain amount of improvement, with the result that other treatment leads to recovery more rapidly than it would otherwise have done. In a small number of cases, especially very chronic ones, the serum appears to have no effect.

I have never seen the slightest benefit follow any form of vaccination, and in some cases the local condition has been definitely aggravated. Several American physicians have told me that they have been quite unable to confirm Bargen's enthusiastic reports about vaccination with his organism, which has not been accepted by any other American workers as the cause of ulcerative colitis.

In my experience the mortality of ulcerative colitis is extremely low. Complete recovery may occur after very long periods of treatment, and in cases which do not respond to serotherapy as much as a year or two of continuous treatment may be required. There is also an unfortunate tendency to relapse. The danger of this is much reduced if treatment is continued until the sigmoidoscope shows no trace of inflammation, even if symptoms have already disappeared for some weeks. Associated conditions, such as oral and pharyngeal infections and anal complications, must be treated, as a relapse may follow an acute sore throat or the development of a perianal abscess or a fistula in ano. The patient should always take sufficient paraffin to keep his stools soft; if achlorhydria is present, the associated gastritis should be treated, and, if the secretion of acid does not return, the patient should take hydrochloric acid for the rest of his life.

PULMONARY TUBERCULOSIS IN CHILDHOOD*

BY

G. B. DIXON, M.R.C.S., L.R.C.P.

CHIEF TUBERCULOSIS OFFICER, CITY OF BIRMINGHAM; MEDICAL SUPERINTENDENT OF THE CITY SANATORIUM

(With Special Plate)

I think it is fair comment to say that in the past too little attention has been paid to the diagnosis and treatment of pulmonary tuberculosis in young children. The non-pulmonary forms of this disease have received more attention and they have given more satisfactory results. The provision of beds in special institutions for pulmonary tuberculosis occurring in children has not been, in relation to the number of cases, so generous as for the non-pulmonary types; this, and the better response to treatment of the non-pulmonary forms, have been contributory factors to the present position. In making use of the term "childhood type" of tuberculosis, I refer to lesions in the lungs and intrathoracic glands which are the result of a first infection with the tubercle bacillus.

INCIDENCE AND COURSE

Figures for the year 1923, published by the National Association for the Prevention of Tuberculosis, show that in England and Wales between 2,700 and 2,800 children

* Summary of an address read to the infant welfare subgroup of the Midland branch of the Society of Medical Officers of Health.

of from 1 to 4 years of age died from tuberculosis. Between 1,300 and 1,400 of these died from tuberculosis of the nervous system (meningitis), about 500 from tuberculosis of the intestines and peritoneum, 400 from disseminated tuberculosis, between 300 and 400 from tuberculosis of the respiratory system, and less than 100 from disease in the bones and joints. In Birmingham, during the years 1915-17, 193 cases of pulmonary tuberculosis were notified among children up to 5 years of age, and during the years 1923-25, 88 cases were notified in children of the same age; for these periods respectively, 73 and 66 deaths occurred. Some figures dealing with the mortality rates for tuberculosis among young children in the Birmingham Children's Hospital were recently published by Smellie,[1] who states that in the period 1922-29, 1,514 deaths occurred in the hospital, and that there were 1,190 necropsies, in 192 of which the cause of death was tuberculosis. He found that the highest mortality occurred among children in the second year of life, and the greatest number of deaths took place in the first four months of the year, the smallest number being recorded during August. The focus of this disease among these children was cerebral in 51 per cent. of the total number dying, abdominal in 33 per cent., and pulmonary in only 14 per cent.; Smellie assumed that the infection was due to the human type of bacillus in no less than 64 per cent. of the series. It may be inferred from these figures either that pulmonary tuberculosis in young children is not a very common disease or that it is not always readily diagnosed.

I think it is generally accepted that pulmonary tuberculosis occurring during the first year of a child's life tends to progress rapidly, and to cause death from acute general tuberculosis or tuberculous meningitis. In the second year the disease may follow a less acute and less rapid course, but there is still little or no tendency to healing, and death usually takes place. After this period, and until the age of about 10 years, acutely progressive and rapidly fatal tuberculosis of the lungs becomes less common. Between the ages of 3 and 10 children may be found with well-marked pulmonary tuberculous lesions, which in some instances do not cause much inconvenience or give rise to any very marked or typical symptomatology. Krause[2] writes:

> "The more I see of tuberculosis in infants and the more I confirm the diagnosis by the aid of new methods, the more infants I find who run along with comparatively little illness."

My own experience bears out this view.

Differences Between Childhood and Adult Tuberculosis

Pulmonary tuberculosis in the child has certain definite characteristics which distinguish it from the same disease in adult life; the infantile type is the result of a primary infection, that occurring in the adult is the result of a reinfection. According to Myers,[3] an area of inflammation develops where the bacilli settle in the lung, which may be small, or large enough to affect an entire lobe; from it the regional hilar and broncho-tracheal glands are quickly involved, and become enlarged. The parenchymatous lesion may heal and almost entirely disappear, a small area of calcification—that is, Ghon's body—being left (Fig. 1, Special Plate). In a comparatively short time the lymphatic glands may show calcium deposits, or they may remain caseous, without calcium deposition. In the infantile type the parenchymatous lesion may be localized in any part of the lung, least frequently in the upper lobes, and after the subsidence of the initial inflammatory changes which occur in connexion with it, may be difficult to demonstrate radiographically. In the adult type the lesion is apical, and the tracheo-bronchial glands are not included in the process of reinfection. Some authorities[4] state that when a tuberculous process exists in any part of the body, even if remote from the lung, tubercle bacilli may be carried to the hilum of the lung, where they cause enlargement of the lymphatic glands, apart from any pulmonary parenchymatous lesion.

In the childhood type, caseous lesions tend to become calcified, and cavitation is rarer than in the adult type; in the adult type, caseous lesions are usually associated with cavitation and fibrosis. It is well to remember in this connexion that the adult type of disease, associated with cavitation, may be found at the age of 7 or 8 years, and occasionally earlier. The distribution of the disease in young children conforms most usually to one of three types—namely, a diffuse miliary form, a localized form in which the lesion may be large or small and represented by a caseous mass with a fibrous periphery or by a massive lobar infiltration, or a broncho-pneumonic distribution. Massive distributions involving the major portions of one or both lungs are occasionally seen as terminal conditions. (See Figs. 2, 3, and 4, Special Plate.)

Diagnosis

The diagnosis of pulmonary tuberculosis in early childhood is seldom an easy matter; the physical examination of infants, who protest both vocally and physically, is not always satisfactory as far as pulmonary conditions are concerned. The information derived from percussion is never so reliable as in the case of adults, and as infants do not expectorate we are cut off from one of our more dependable sources of information. In addition, infants are usually difficult subjects for radiography; this is unfortunate, as we have to rely more upon radiographic investigation in infants suspected of pulmonary tuberculosis than we do in the case of adults. Certain special signs have been described in relation to the diagnosis of intrathoracic glandular tuberculosis in children, the better known of which are D'Espine's sign and Eustace Smith's sign; I place slight reliance upon the evidence that their presence is supposed to furnish.

In many cases physical examination alone gives insufficient evidence upon which to base a diagnosis. The history of the case is important. Exposure to tuberculosis within the family is significant, and a history of attacks of phlyctenular conjunctivitis, of erythema nodosum, or of pleurisy is suggestive of tuberculous infection. Symptoms, as a rule, do not help us much; they may be absent, or if present are for various reasons not always elicited. When they exist they may vary in intensity from those associated with a so-called cold to those accompanying a pneumonia. Cough, loss of weight or failure to increase weight, increased respirations, pyrexia, peevishness, and vomiting may all be present, and in the absence of discovery of other ascertainable cause should be regarded with suspicion.

Radiographic Methods

Radiography is one of the most useful and valuable methods of diagnosis at our disposal, but a negative radiographic examination should not in every instance refute a diagnosis of tuberculosis otherwise arrived at. The lesions in parenchyma or hilum may cast no shadow on the film. The hilum alone may show evidence of disease, the initial lesion being in some remote part of the body; if in the lung, it may be obscured by the diaphragm, ribs, or heart, and for this reason be difficult to detect, though it is usually demonstrable microscopically or macroscopically after death. The tracheo-bronchial glands,

when enlarged, cannot always be demonstrated radiographically, because of their position within the mediastinum, where they are masked by the heart and large blood vessels; but any abnormal deviation of the trachea occurring in childhood should always suggest the presence of enlarged tracheo-bronchial glands.

McPhedran[4] says he

"has not seen in radiographs of the excised or living lung, non-tuberculous enlargement of the intra-pulmonary glands sufficient to allow them to be radiographically recorded."

In this statement he refers particularly to bronchitis, broncho-pneumonia, and the chronic non-tuberculous pulmonary lesions. He also finds that

"The differentiation between the shadows cast by tuberculous hilar glands and normal anatomical structures, such as blood vessels, is at times difficult. Homogeneous rounded or oval densities suggest vessels running parallel to the axial ray, particularly if somewhat symmetrical bilaterally. Although calcification in the glands of both hila is not uncommon, it is rarely that one or more do not show characteristic irregularity of contour and inequalities of density. When densities of uncertain origin appear, decision as to their character may be facilitated by radiographing the patient again, after rotation, when, if due to the blood vessels, they will disappear."

The presence of calcium deposits in the tracheo-bronchial glands, or in the hilar glands, is nearly always associated with a tuberculous infection. Pleurisy probably occurs more frequently among children than is generally realized, and in many cases results from a tuberculous infection; the fibrinous type is more frequent than the serous, and it should be realized that a well-marked pleural rub may exist without any definite *x*-ray evidence of its presence. Tuberculous intrathoracic disease can often be demonstrated radiographically when it exists, if satisfactory antero-posterior and oblique films are made. It is injudicious to express a dogmatic opinion in any case if the *x*-ray examination has consisted of screening alone.

Laboratory Methods of Examination

These may provide conclusive evidence for a positive diagnosis. Smears of faeces should be examined for the presence of acid-fast bacilli, and, if these are found, an animal experiment should be carried out to ascertain if they are tubercle bacilli. Such examinations, undertaken in some hundreds of children under 8 years of age admitted to the sanatorium for observation, showed the presence of acid-fast bacilli in about 1 per cent. of the specimens examined, and in practically every instance animal experiment proved them to be tubercle bacilli. A more recent, and possibly more exact, method of finding tubercle bacilli in the digestive tract is to examine the centrifuged deposit from a gastric lavage, undertaken after the child has been fasting for six or eight hours. From 130 c.cm. to 300 c.cm. of sterile water are required for the purpose. The tube and glass funnel or syringe body used must be previously sterilized, as must the bottle used for collection. The fluid is centrifuged and the sediment is stained for acid-fast bacilli; some of the sediment should be plated on a suitable medium and some injected into a guinea-pig, either or both of which methods may give a positive result when suitably stained specimens of the sediment are negative.

Tuberculin Tests

For infants the two most reliable tuberculin tests are the quanti-Pirquet test of Morland and the intradermal test (Mantoux). Dilutions of old tuberculin, human or bovine, or both, may be used. For the former, dilutions of 1, 4, 16, and 64 per cent. are used, the skin on the inner side of the forearm being a suitable site for application. After cleansing the skin, five abrasions are made, and small amounts of the progressive dilutions are applied from the wrist upwards, the fifth abrasion acting as a control. After twenty-four, and again after forty-eight, hours the arm is examined, and the diameter of any resulting papule is measured with calliper and rule. The amount of traumatic reaction is indicated by the measurement of the fifth abrasion, and this is subtracted from that of the other papules; the results are recorded after each examination and measurement. From these two readings the average papule size and the average papule difference are estimated, and are compared with Morland's modification of Erlandsen's table,[5] when a unit of sensitivity can be arrived at which is useful for purposes of comparison and for records.

For the intradermal test a suitably graduated tuberculin syringe, fitted with a No. 24 gauge half-inch needle, and old tuberculin are used. In the first place, a solution of tuberculin—0.01 mg. in 0.1 c.cm.—is injected parallel to the surface, into the superficial layers of the skin. If no reaction results in twenty-four to ninety-six hours, the procedure is repeated with a solution of which 0.1 c.cm. contains 0.1 mg. of tuberculin; in the absence of reaction within five days, the test is repeated with a solution of which 0.1 c.cm. contains 1 mg. of tuberculin. If no reaction occurs after any of these, it may be assumed that the child has not been infected. When a positive reaction occurs, it is usually evident within twenty-four to forty-eight hours, appearing as a deep red nodule surrounded by a pink halo. A tuberculin reaction when positive cannot be accepted alone as evidence for the necessity of treatment; it merely indicates that the person has been infected, and to be infected has not the same significance as to be affected, although infants giving a strong positive reaction without evidence of active or latent tuberculosis should always be kept under supervision and examined from time to time. If reaction occurs and is associated with latent tuberculosis, it is advisable to keep the child under constant supervision, and to advise such prophylactic measures as extra nourishment and admission to an open-air school. By latent tuberculosis[6] I mean a lesion which is unaccompanied by symptoms evident to patient or friends, or by physical signs recognizable by the physician, and which is detected only by tuberculin reactions and by characteristic changes shown on *x*-ray films. In relation to the various tuberculin tests, it should be recalled that in grave tuberculosis the test may be negative, and sensitivity may be reduced or absent after pneumonia, enteric fever, influenza, pertussis, or measles, and in other conditions affecting adults, among which is pregnancy.

Reviewing the various points upon which we may depend for a diagnosis, I would rely upon the following factors:

1. The presence of physical signs and symptoms.
2. Definite involvement of the parenchyma, lung hilum, or both, as revealed by *x*-ray examination.
3. A positive reaction to a tuberculin test.
4. The demonstration of tubercle bacilli.
5. A history of exposure within the family.

The first and fifth may be very difficult to establish, and their absence should never be regarded as conclusive evidence in ruling out a diagnosis of tuberculosis. The fourth, too, is not always positive, and although conclusive when present, is no more a *sine qua non* than the presence of a positive sputum in adults. A positive tuberculin test and a positive *x*-ray examination, when other causes for the condition in the lung have been ruled out, may be accepted as sufficient for a positive diagnosis in many cases.[7]

PROPHYLAXIS

The incidence and death rates for tuberculosis among adolescents are high in this country, and are said to be so because the "infantile period," as far as tubercle is con-

cerned, is the "neglected period" from the point of view of diagnosis and treatment. In the past we have given much attention to the isolation and palliative treatment of large numbers of chronic infectious cases of tuberculosis in Birmingham, removing the patients from their homes to hospital pavilions in sanatoriums, in an endeavour to prevent spread of infection among other members of the family. This procedure has possibly influenced the accelerated decrease in the tuberculosis mortality rate which has occurred during recent years in Birmingham. The percentage decrease[12] between the five years 1883 to 1887, and a similar period 1898 to 1902, was 4.15, while the percentage decrease between the five years 1903 to 1907, and a similar period 1918 to 1922, was 24.24.

In my opinion, rigorous and compulsory segregation of all infective cases would in many instances be a harsh procedure, and might defeat the end in view; voluntary segregation, however, practised benevolently and secured by tactful and sympathetic persuasion, should be aimed at. If this is to succeed, the patients with advanced disease should not be exposed to the open air to the same extent as ambulant patients, and, so far as visitors and recreations are concerned, they may with advantage be granted concessions which would not be given to more robust patients with early disease. The object is to get them into the sanatorium for long periods as often as possible when they are infective, unable to work, and ineffectively isolated at home. The larger the percentage of deaths from pulmonary tuberculosis occurring in these hospital pavilions the better for the community. This alone is insufficient to break the vicious circle of tuberculosis infection within the family, unless at the same time vigorous measures are adopted to diagnose and treat tuberculosis in infancy and early childhood, which would be facilitated if the departments dealing with infant welfare and tuberculosis co-operated more closely. The infant welfare departments would help greatly by passing on to the tuberculosis department definite and suspected cases of tuberculosis, or any infants who gave a positive tuberculin reaction, in order that both the infant and the family of which it was a member might be investigated. A positive tuberculin reaction in an infant is frequently the first indication of the presence of tuberculosis in the family circle,[13] and the suspected child is often the first link in a chain of events leading to the diagnosis of tuberculosis in a parent. Measures designed to prevent the spread of tuberculosis can only be regarded as efficient if the family is treated as the unit for investigation.

The number of contacts which can be examined in any clinic depends entirely upon the size of the medical staff, but a majority of the cases dealt with should be children, and they should be kept under supervision for long periods, with re-examination at intervals, and the investigation should always include an *x*-ray examination and a tuberculin test. Arrangements should be made to prevent, as far as possible, continuous exposure of the contact child to infection. Co-operation between the two departments might also be extended to provide residential accommodation for the ante-natal and maternity care of pregnant women suffering from pulmonary tuberculosis. After the puerperium, these patients should be admitted to sanatoriums for prolonged periods, and their infants might be placed with advantage in a pavilion attached to a babies' hospital, which would fulfil the requirements of a "preventorium." Such arrangements would mean additional expenditure, but if they helped to lessen an appreciable amount of infantile infection and subsequent adult disease they would be justified.

The use of pasteurized milk[8] has been shown to diminish the mortality rate from non-pulmonary tuberculosis between the ages of 1 and 4 years, but has little effect upon the mortality rates during the first year of life. The first infection of a young child with tuberculosis is said by some authorities to confer a certain amount of immunity, but this is not always sufficient to withstand massive doses and continuous exposure. If the primary tuberculous infection of a child is not overwhelming and lethal in its effect, a condition of latent tuberculosis may result. Opie[10] suggests that latent tuberculosis increases resistance and occasionally affords complete protection from subsequent disease; it is nevertheless a source of danger, because it may be transformed into active progressive disease, and any immunity it confers should be regarded as limited and transient only. In adults[11] who show no scars of an infantile infection, and who subsequently develop tuberculosis, the disease assumes the characteristics of childhood infection, and may pursue a rapidly fatal course. This has been observed particularly among the negro races, and suggests that infantile infection confers some immunity.

Production of Immunity

In recent years attempts have been made to produce immunity in infants by the inoculation of tubercle bacilli that have been attenuated in virulence. Calmette and his fellow worker Guérin have practised this extensively. The method adopted is to give by the mouth 1 cg. on the third, fifth, and seventh days of life. If a positive tuberculin reaction does not result, they suggest giving one-fortieth to one-twentieth of a centigram of the vaccine subcutaneously. Where this is done a positive tuberculin reaction is obtained within six to eight weeks. About 200,000 infants are reported to have been treated in this way. Calmette's views as to the freedom from danger of this method of treatment have not been universally accepted. Fears have been expressed that an avirulent strain of bacilli, when injected into the human body, might regain its virulence.

CONCLUSIONS

In our attempts to prevent tuberculosis we cannot emphasize too strongly or too frequently that it is a communicable disease, and that it is therefore a family disease; when an adult in the family suffers from the disease and no precautionary measures are taken, it has been shown that he may infect 50 per cent. or more of the younger members of the family. It follows, therefore, that the family as a whole, and not the patient alone, should be the unit for investigation and continued supervision. Children with active disease should be given prolonged periods of treatment in a sanatorium in which provision is made for the schooling of those whose condition allows of it. Children with latent tuberculosis, and those who give a positive reaction to the tuberculin test, should be kept under supervision for prolonged periods. Everything possible should be done to provide them with adequate food and clothing, and to remove them from continuous exposure to infection in the home.

The radiographs illustrating this article were taken by Mr. W. H. Smith.

PULMONARY ARTERIO-SCLEROSIS

BY

C. G. PAINE, M.B., B.S.

CLINICAL PATHOLOGIST, ROYAL INFIRMARY, SHEFFIELD

AND

ROBERT PLATT, M.D., M.R.C.P.

MEDICAL REGISTRAR, ROYAL INFIRMARY, SHEFFIELD

(*With Special Plate*)

The term pulmonary arterio-sclerosis implies a disease or syndrome the outstanding features of which are referable to arterio-sclerosis of the lesser circulation, this lesion being the predominant pathological finding. Whether or not the involvement of the pulmonary arteries is secondary to pre-existing disease—syphilitic or non-syphilitic—of the lungs themselves, if the results of such involvement alter the entire course of the disease and produce a recognizable clinical picture of their own, the term will still have its significance in diagnosis. The word "arterio-sclerosis" we retain as being clinical rather than pathological, and implying any change leading to thickening of the vessel wall. The syndrome of pulmonary arterio-sclerosis has also been described under the name of Ayerza's disease, or Ayerza-Arrillaga's disease, but as some writers have restricted the use of these terms to cases of syphilitic origin, and as neither Ayerza nor Arrillaga has an undisputed claim to being the first to recognize the syndrome, it appears preferable to adhere to a more descriptive terminology.

Vieussens in 1706 was probably the first to describe the pathological condition of pulmonary arterio-sclerosis. Ayerza in 1901 described in clinical lectures the syndrome of right ventricular hypertrophy, cyanosis, and polycythaemia (cardiacos negros) in patients with certain chronic pulmonary disorders, which his pupil Arrillaga, in a thesis published in 1913, correlated with the anatomical finding of sclerosis of the pulmonary artery. Posselt[1] (1908) had, however, already published his paper describing the clinical and pathological features. Cheney[2] in 1927 described two cases, and gives in his paper a complete bibliography (forty cases in all) up to that date. About twenty-five more have since been described. In the majority of the reports the diagnosis has been made only after the patient's death, and it therefore seems to be of sufficient interest to record here three cases, in which a clinical diagnosis of pulmonary arterio-sclerosis was made, together with details of the post-mortem findings.

CASE I

Female, aged 52, married. First seen by one of us on February 5th, 1928. She had suffered from bronchitis, especially in the winter, for many years, and had noticed gradually increasing dyspnoea on exertion. About four months previously there had been a rather rapid change for the worse; since then she had been confined to bed, the chief symptoms of this latter period being swelling of the legs, abdomen, and arms, more severe dyspnoea, and cyanosis of the face, mucous membranes, and extremities. The patient was propped up in bed, but lying over towards her right side, in which position breathing was not obviously distressed so long as she remained still. Cyanosis was extreme, and of a deep blue-purple shade. There was pronounced oedema of the legs, back, and arms (especially the right arm), and extreme ascites, so that the abdominal organs could not be examined. There was considerable emphysema, bronchitis, and congestion of the bases of the lungs. The apex beat of the heart could not be made out, but the right border appeared to be at least one and a half inches to the right of the sternum. The heart sounds were normal. There was no pronounced arterio-sclerosis of the brachial, radial, or retinal arteries; the blood pressure was 130/70. A provisional diagnosis of pulmonary arterio-sclerosis was made, and she was admitted to the Royal Infirmary under Professor Mellanby on February 6th, remaining in about the same condition until midnight of March 23rd, when she vomited a large quantity of blood, and died. During the time she was in hospital the urine was scanty, of fairly high concentration (specific gravity 1020 to 1026), and contained a trace of albumin. The blood count on February 8th showed 6,480,000 red cells per c.mm., haemoglobin 100 per cent., white cells 8,400 per c.mm. A paracentesis of the abdomen was performed, 13½ pints of clear fluid being removed. Owing to the oedema, four attempts to remove blood from a vein (for Wassermann test) were unsuccessful.

At the post-mortem examination a generalized oedema, most marked in hands and feet, was found. There was marked oedema of all tissues internally. The pericardium showed increase of clear, straw-coloured fluid, "milk-spots" on right ventricular wall. There was a marked dilatation and hypertrophy of right ventricle; right auricle dilated; valves normal. Very little atheroma of the aorta present. Trachea normal; extensive oedema of lungs, resistant on section; marked atheroma of pulmonary artery, especially in the smaller branches; emphysema of anterior borders of the lung. Excess of clear fluid in pleurae. Apical adhesions on both sides. Other organs showed changes of passive congestion, and do not warrant special description. Histological examination demonstrated atheroma of pulmonary artery and its branches. There was an apparent increase in fibrous tissue round the smaller vessels, but there was no sign of any change in the muscle or intimal coats. Elastic tissue of vessels normal. Oedema, slight anthracosis, catarrhal bronchiolitis, and emphysema were also present.

CASE II

Female, aged 63, married. She was admitted to the Royal Infirmary under Dr. Yates on the evening of November 11th, 1929. She had always had good health until two years before, when she first noticed shortness of breath on exertion. Some months later she noticed swelling of the ankles, which was more pronounced towards evening. In the previous seven weeks she had become very much worse, the swelling having spread to the abdomen. According to her husband, she had some "winter bronchitis" for a few years, and had been cyanosed for some weeks. On examination extreme plum-coloured cyanosis was present, but the patient at rest in bed, with the head and shoulders supported, was not markedly dyspnoeic. There was considerable oedema of the legs, and a large ascites. The left border of the heart was 4 inches, the right 2½ inches, from the mid-line. The heart sounds were normal. The liver dullness extended 4 inches below the right costal margin. The blood pressure was 130/62. There was no pronounced general arterio-sclerosis. The lungs showed no great degree of emphysema, but adventitious sounds were present throughout. The patient was too ill for a very thorough examination to be made, and died three days after admission. The diagnosis of pulmonary arterio-sclerosis was made by exclusion of other conditions which could account for such a degree of cyanosis and failure of the right ventricle. Unfortunately a blood count and Wassermann test were not performed before the death of the patient.

Post-mortem Examination.—Pericardium: excess of clear fluid. Heart: dilatation and hypertrophy of right side; myocardium dark and firm; fibrosis in tips of papillary muscles on the right side; atheromatous plaques at bases of mitral and tricuspid valves; no stenosis. Aorta: atheroma at efflux of great vessels; atheromatous ulceration and calcification in abdominal aorta. Pulmonary artery and branches: marked atheroma. Trachea normal. Lungs: marked congestion at both bases; emphysema of both anterior borders; vessels showed numerous atheromatous plaques, most marked in areas midway between hilum and pleura; in places the lumen of the vessels was almost occluded. Pleurae: excess of clear fluid. The remainder of the organs showed no abnormality except passive congestion. Material from lung near hilum on histological examination showed atheroma, with slight medial hypertrophy; material from half-way between hilum and pleura showed most pronounced changes. There was a slight degree of emphysema, with oedema, congestion, and areas of haemorrhage. The smaller vessels of the pulmonary circulation were greatly thickened owing to medial hypertrophy. No intimal changes were noted. The bronchial vessels were in all areas quite normal. (See Figs. 1 and 2, Special Plate.) Some anthracosis and catarrhal bronchiolitis were present.

CASE III

Female, aged 46, married. Admitted to the Royal Infirmary under Dr. Yates, January 27th, 1931. For thirty years she had suffered from bronchitis and shortness of breath. In October, 1930, she had a severe headache and "turned dizzy," after which she was unconscious for two days. Since then she had been confined to bed, the legs having become swollen; she had been very short of breath on moving about in bed. On examination there was orthopnoea and extreme plum-coloured cyanosis. There was marked clubbing of the fingers. The legs and back were oedematous, and there was moderate ascites. The movements of the chest were symmetrical, but very restricted. Air entry poor. The percussion note was resonant throughout, breath sounds vesicular, with generalized rales and rhonchi. The apex beat of the heart was in the sixth interspace, and somewhat diffuse; the left border was 5½ inches, the right 1½ inches, from the midline. A systolic murmur was heard in the mitral area, conducted towards the axilla. The liver was enlarged to a level 3 inches below the costal margin. The sputum was mucopurulent, and contained no tubercle bacilli. The red blood count was 5,200,000 per c.mm., haemoglobin 85 per cent. Albumin was present in the urine, which was scanty and of normal concentration (specific gravity 1012 to 1020). The non-protein nitrogen of the blood was 43 mg. per 100 c.cm. The Wassermann reaction was negative. The combination of right-heart failure, with extreme cyanosis and the history of chronic bronchitis, suggested the possibility of pulmonary arterio-sclerosis, especially as there was no pronounced emphysema. There was no marked change in the patient's condition during her stay in hospital, and she died on February 19th, apparently from heart failure.

At the post-mortem examination the pericardium was found to contain excess of clear fluid. Gross dilatation of heart and hypertrophy of right side; left side normal. Muscle pale, but firm; no fibrosis or fatty degeneration. Valves: slight atheromatous change at base of mitral and aortic cusps; marked atheroma at base of tricuspid flaps. Aorta: very little atheroma. Pulmonary arteries showed marked atheromatous change. Pleurae: excess of clear fluid. Lungs: dark in colour; bronchi very firm and stood out above the cut surface, filled with thick tenacious muco-pus; marked oedema at both bases; very small vessels just beneath pleura remained patent, and stood out above the cut surface; slight anterior border emphysema, of compensatory type. Mediastinal glands: marked carbon pigmentation. Other organs showed evidence of passive congestion only. On histological examination the lungs showed marked passive congestion. Bronchi and bronchioles gave evidence of long-standing inflammation; there was pronounced muscular hypertrophy, submucous fibrosis, and formation of granulation tissue. The contents of the lumen demonstrated a catarrhal bronchitis, and in places there was a squamous metaplasia. The bronchial arteries were normal throughout. The pulmonary artery and its main branches showed marked atheroma. Some of the smaller pulmonary arteries were normal; others showed extreme degrees of arterio-sclerotic change. There was a well-marked muscular hypertrophy; whereas the bronchial arteries in cross-section were flattened, these remained circular. This was accompanied by hypertrophy and reduplication of the internal elastic lamina. Internal to this was a very exuberant proliferation of the subintimal connective tissue. (See Figs. 3 and 4, Special Plate.) Within this subintimal fibrous hyperplasia were found small vascular channels, giving the appearance of recanalization after thrombosis, but the muscular hypertrophy and elastic reduplication denoted that the change was an arterio-sclerotic and not a thrombotic one.

DISCUSSION

The cases described have occurred in a series of 700 post-mortem examinations, and are therefore of some rarity. The three examples have one feature of their morbid anatomy in common—namely, extensive atheroma of the pulmonary artery and of its branches. Pulmonary atheroma is a concomitant of pulmonary arterial hypertension. Hypertension may be due to theoretical pressor substances, or to mechanical obstruction, which may act in the venous, capillary, or arterial parts of the circulation. Mitral stenosis is the commonest cause of pulmonary atheroma, and is an example of venous obstruction. Capillary obstruction is exemplified by emphysema, wherein there is a marked reduction in the total capillary bed. Pulmonary arterio-sclerosis is the example of obstruction to the arterial portion of the lesser circulation, and the arterial changes bear a striking resemblance to those found in chronic interstitial nephritis.

At post-mortem examination none of the three cases showed any valvular lesion. All three showed varying degrees of emphysema, together with signs of passive congestive heart failure. Microscopically, two of the cases disclosed hypertrophy of the muscular coat of the pulmonary arteries, and one of these had a secondary subintimal hyperplasia in the small vessels of the lung tissue adjacent to the pleural surface. A striking feature was that the bronchial arteries, being members of the systemic circulation, showed no change in the muscle coats, the sclerosis being confined entirely to the pulmonary vessels. Other features worthy of mention were an absence of microscopical evidence of syphilis and the presence of chronic bronchitis and bronchiolitis. Thus, right-heart failure, the cause of death in all three cases, was due in the first case to emphysema, and in the others to pulmonary arterio-sclerosis, all three being complicated by inflammatory disease of the bronchi and bronchioles.

The clinical features of the three cases were very similar, and fit in well with the descriptions in the literature, yet in the first case histological examination failed to reveal evidence of pulmonary arterio-sclerosis (other than atheroma) sufficient to warrant the case being recorded as an example of this syndrome. It appears, therefore, that with the clinical methods at present available only a provisional diagnosis can be made, microscopical examination of the lung being necessary before final proof is established. Pulmonary arterio-sclerosis is not the only syndrome, however, in which clinical diagnosis is somewhat uncertain, and a summary of the outstanding features which suggest the diagnosis is therefore not without importance.

The disease, whether syphilitic or otherwise, is preceded by a bronchitic stage, which may last for many years, and takes the form of chronic bronchitis with mucoid or muco-purulent sputum, and occasionally haemoptysis. The cardiac stage, which succeeds this, is divided by Nathan[3] into a period of compensation, in which the colour is reddish-purple, the right heart enlarged, the pulmonary second sound loud, and polycythaemia present, and a final stage of right-heart failure (cardiopathie noire, cardiacos negros) in which the patient develops the typical extremely deep blue-violet, or almost black, cyanosis, with generalized oedema, congestion of the lungs, haemorrhages, somnolence, and sometimes anginal pain. Clubbing of the fingers has been noted, but is not a constant finding. It was present in only one of our cases. According to Yater and Constam,[4] radiograms reveal a widening of the pulmonary artery with enlargement of the right auricle and ventricle, but no increase of the pulmonary veins or left auricle. Points which seem to us most suggestive of the diagnosis are: (1) a history of chronic pulmonary disease (bronchitis); (2) the presence of extreme cyanosis out of all proportion to the degree of dyspnoea, accompanied by polycythaemia, and enlargement of the right heart without valvular disease; (3) rapid development of oedema, which often affects the arms as well as the legs and abdomen. The diagnosis is more certain in the absence of pronounced emphysema.

LINES OF ARRESTED GROWTH IN THE LONG BONES OF DIABETIC CHILDREN

BY

H. A. HARRIS, D.Sc., M.B., B.S.

ASSISTANT PROFESSOR, INSTITUTE OF ANATOMY, UNIVERSITY COLLEGE, LONDON; ASSISTANT TO THE MEDICAL UNIT, UNIVERSITY COLLEGE HOSPITAL

(*With Special Plate*)

During the last seven years the rate of growth of the long bones in health and disease has been studied radiographically with a view to ascertaining the susceptibility of bone to nociceptive influences.[1 2 3] As the acute exanthemata in children consistently produced an arrest of growth which was accurately registered in the radiograms of the long bones, the problem arose whether the metabolic disturbance of growth was due to pyrexia, anhydraemia, or deficiency or unsuitable intake of food. Accordingly opportunity was taken to examine cases of disease presenting no pyrexia. Diabetic children were therefore examined radiographically, with the result that multiple lines of cessation of growth were found to be a constant feature whenever the disease was of long standing. Three cases have been selected as illustrative of the simultaneous control by insulin of the disease and of growth.

CASE I

A girl, aged 13, was brought to the Mayo Clinic in March, 1924, with a history of an acute onset of diabetes three weeks previously. The condition was controlled by the administration of 10 units of insulin night and morning. Owing to the occurrence of abnormal variations in the general condition, the parents permitted the child to go to hospital for subsequent periods of about ten days in October and November, 1924, in May and June, 1925, and in June, 1926. A radiogram of the knee joint of this patient, for which I am indebted to Dr. Russell M. Wilder, displays multiple lines of arrested growth (Fig. 1, Special Plate). In May, 1925, a note was made by Dr. Wilder that the patient was "following the regime reasonably conscientiously, and has been sugar-free at all times except twice after dietary indiscretions." Menstruation began in November, 1925, and was regular until March, 1926, then influenza was followed by dysmenorrhoea and amenorrhoea. A radiogram of the chest showed healed tuberculosis of the upper left lobe.

The radiogram shows more than ten transverse lines in the diaphysis of the femur and of the tibia. Obviously, the clinical history is not sufficiently detailed or accurate to determine those lines of cessation of growth due to influenza, those to uncontrolled diabetes, those to dietary excess whilst taking insulin, and those to negligence in regularity of the insulin treatment. The multiplicity of the lines indicates the variations in the rate of growth in the patient, negatives the view that the lines are seasonal, and illustrates the difficulties involved in ascribing to a given line the exact cause of the arrest of growth.

CASE II

A girl, aged 12, was under the care of Professor T. R. Elliott for a period after August, 1923, when she was admitted to hospital with glycosuria. Insulin was administered and the glycosuria was controlled. The patient was readmitted in October, 1923, in May and July, 1924, in March, August, and October, 1927. Throughout the period the glycosuria was fairly well controlled. Any failure brought the child to hospital for further alteration in the diet or in the insulin dosage. The only acute infection suffered by this child was chicken-pox in March, 1927.

The radiogram (Fig. 2, Special Plate) taken in November, 1927, shows a series of distinct transverse lines of arrested growth. Eight transverse lines can be clearly identified on the radiogram, and these correspond closely with the seven admissions to hospital and the one attack of chicken-pox.

CASE III

A boy, aged 6½, was admitted to hospital in January, 1928. He had an excessive appetite, much thirst, and was losing flesh. Sugar had been detected in the urine one week previously, when he developed an attack of diabetic coma. This child, formerly very bright and active, had no experience of illness until he was four years old, when he had chicken-pox, with attacks of "asthma," which appeared frequently as an expression of any slight "cold." The boy had mumps in May, 1925, and severe measles in April, 1926. He responded well to insulin treatment, and now, at 7 years of age, weighs 55 lb.

A radiogram of the knee-joint, taken in January, 1928, shows a well-marked line of arrested growth in the diaphysis of the femur and of the tibia at a distance of about 1.5 cm. from the epiphyseal cartilage. This distance corresponds to the average amount of growth in the shaft at this age for a period of fourteen to twenty months, and one is justified in suggesting that this line is attributable to the attack of measles in April, 1926. Between the epiphyseal cartilage and the diaphysis is a band of dense calcareous deposit due to the arrest of growth resulting from the acute attack of diabetes. It will be of interest to watch this child further.

COMMENTARY

Lines of arrested growth in cases of diabetes were shown before the Anatomical Association in 1926,[1] and again by Professor Elliot Smith[4] in the same year. In September, 1927, Morrison and Bogan,[5] in the routine examination of sixty-eight diabetic children, discovered thirty-six cases with multiple transverse striae. They state that the transverse striae of the long bones are found in a larger percentage of diabetic than of normal children, but failed to associate the transverse lines with the onset of the disease. It is obvious that for the explanation of cases presenting multiple lines a complete clinical history of all infectious diseases, both severe and mild, is essential, since it has already been shown that the bone registers the arrest of growth to an extent which is more delicate in many cases than the subjective symptoms of the patient.

Radiographic examination of the long bones at stated intervals is a valuable means of recording the repeated arrests of growth in children suffering from metabolic diseases such as diabetes. The lines of arrested growth tend to persist in the bones adjoining joints with a movement essentially monaxial—for example, ankle or knee. The bony lines of arrested growth are absorbed rapidly at the wrist and elbow in accordance with the rapid remodelling in an area subjected to bending strains and torts. Moreover, the rate of absorption is determined largely by the degree of function, so that the bed-ridden child tends to preserve these lines in the bones of the lower limb, whereas in the upper limb the movements involved in eating, playing, and fidgeting lead to rapid absorption of the lines of dense bone in conformity with the continuous process of change which characterizes the functional use of the part.

CONCENTRATED ANTIPNEUMOCOCCAL SERUM IN THE TREATMENT OF LOBAR PNEUMONIA

BY

R. R. ARMSTRONG, M.D., F.R.C.P. AND R. S. JOHNSON, M.D., M.R.C.P.

(Research Laboratory, St. Bartholomew's Hospital)

(*With Special Plate*)

The following case appears to be of exceptional interest, as it illustrates unusual features in the onset, treatment, and termination of primary lobar pneumonia.

Clinical History

A robust young man, aged 19, was admitted to hospital at midday with a clinical history of the onset, at 8 o'clock in the morning, of sudden severe abdominal pain, chiefly in the left upper quadrant. He had nausea, but no vomiting; the bowels had acted that morning. There was no history of dyspepsia or of any abdominal symptom, no rigor, and no cough.

The pain continued, and was of such an agonizing character that the patient was immobilized and almost speechless. His face was drawn and livid, pulse 110, respirations 24, temperature 97° F. The abdomen was as rigid as a board, and extremely tender. The liver dullness was normal; no urine was available; rectal examination was negative; there were no physical signs in the lungs.

Under general anaesthesia (gas, oxygen, and ether) the abdomen was opened from the costal margin to the umbilicus by a right paramedian incision. A careful examination was made, of the stomach in particular, but nothing abnormal was found. The abdomen was closed without drainage.

The possibility of acute lobar pneumonia remained to be considered, and events soon confirmed a tentative diagnosis of this disease, for the temperature began to rise, and by evening a pleural friction was detected in the right axilla.

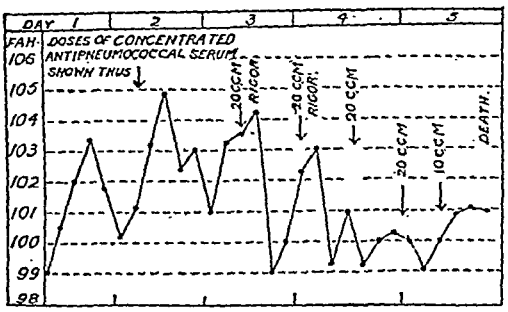
The picture of lobar pneumonia had become clear by the following day, there being widespread pleural friction and impairment of percussion note on the left side, and that evening, thirty-two hours from the onset of his illness, the patient expectorated a fleck of dark, heavily blood-stained sputum. The second day passed with every symptom of a lobar pneumonia of increasing severity, the pulse rate at night reaching 180 per minute. Forty-eight hours from the onset of the illness a radiograph of the chest was taken (Fig. 1, Special Plate), and the report was as follows:

Heart and trachea: not displaced. Right lung field: the upper zone is clear. There is an opacity in the mid zone, and in the lower zone an extension downwards towards the diaphragm of the hilar shadows. Left lung field shows a uniform opacity from apex to base, which is slightly clearer in the upper zone than towards the base. The appearances are consistent with a pneumonia of the left base, with either consolidation or thickened pleura above this. There is also an inflammatory lesion of the right mid and lower zones, which is either resolving or has not yet reached the stage of complete consolidation.

Examination of the sputum, which was now copious, fluid, and deeply blood-stained, showed large numbers of pneumococci. Type was determined in four hours by the rapid method described in the *Journal* of February 7th (p. 214),[1] and 20 c.cm. of the corresponding Type I concentrated antipneumococcal serum (Wellcome) was immediately administered intravenously, sixty hours from the onset of symptoms.

The patient was now desperately ill, and all the classical signs of consolidation of the left lung were present. The patch of pleurisy in the right axilla persisted, with accompanying bronchitis. The heart was normal in size and position. There was a well-marked albuminuria. No immediate shock accompanied the serum injection, but a rigor followed within an hour, as depicted on the Chart.

Twelve hours later, in the morning, cyanosis and distress were less evident, the mental state was clearer, and the toxaemia obviously reduced. There was undoubted improvement. A further intravenous dose of 20 c.cm. of concentrated serum was administered, and this dose was repeated twelve hours later. Whereas a vigorous rigor without sweating had followed the morning dose, the evening administration caused little disturbance, but was followed by profuse perspiration. Progressive improvement was noted throughout this, the third day, in the mental state, in cyanosis, and in the character and frequency of the respiration. The tongue became moist and cleaner. The only adverse feature was a persistent tachycardia, rate 160, uninfluenced by full doses of digitaline during three days. In other respects the pulse was of good quality. The fourth dose of 20 c.cm. of serum was given ninety-six hours after the onset. The patient had so far improved as to demand solid food; the tongue was clean.



Careful examination of the chest left no doubt in our minds that the left lung was consolidated; typical impairment on percussion and loud bronchial breathing were present, as before, on the left; the physical signs on the right were likewise unchanged. The heart was normal in position and size, but tachycardia still persisted; it seemed permissible to attribute this frequency in part to apprehension, for the patient was much concerned about his illness. The urine was now free from albumin. At 6 p.m. the pneumonia appeared to have abated further, and the patient was drowsy and comfortable. A final dose of 10 c.cm. of serum was given, making a total of 90 c.cm. Later in the same evening, however, he became restless, and the house-surgeon, on examining the chest, found an entire absence of breath sounds over the left lung, with gastric resonance rising in front to the level of the fourth rib. The patient vomited a black fluid, and his restlessness increased. He collapsed, and suddenly died, apparently of heart failure, at 4 a.m., 114 hours from the onset of the illness.

Post-mortem Findings

A partial necropsy was performed through the abdominal wound. Except for some plastic fibrin covering the peritoneal surface of the incision—clearly reparative—the wound and peritoneal cavity were healthy. The stomach was enormously dilated, and was filled with a thin, brown-black fluid; it was thrusting up the left cupola of the diaphragm so as to encroach on the left pleural cavity. When the diaphragm was opened the left lung was found almost entirely covered by a layer of soft yellow fibrin, a quarter of an inch in thickness, by which the parietal and visceral pleurae were loosely connected, the pleural surface of the left cupola of the diaphragm being especially involved in this process. The lung was completely collapsed, flabby, and airless. On section, the cut surface was dry; there was no evidence of consolidation or of bronchitis. The fibrin envelope was loosely adherent, and easily peeled off the surface of the lung. The condition is shown in Fig. 2 (Special Plate); the fibrin shell has been stripped to show the wrinkled surface of the collapsed lung. The right lung, by comparison, was voluminous and appeared larger than a normal lung, the upper part being emphysematous. Small slate-grey areas of collapse were present only at the base. On section some congestion but no consolidation, was found; the patch of pleurisy identified during life was confirmed. The heart appeared normal in every respect, chambers not dilated, muscle firm, no pericarditis.

Microscopical Appearances

Sections of the lung, studied under the microscope, confirmed the gross appearances. There was general congestion of the vascular system, and here and there red cells had

extravasated from congested or ruptured capillaries into the alveolar lumina. At the periphery of the lung the alveoli were collapsed, and contained a few desquamated epithelial cells. At the hilum the alveoli, although not distended, contained serum, alveolar epithelial cells, and a few polymorphocytes; pneumococci were clearly seen in some of these alveoli and in places in the perivascular lymphatics. Some alveoli were crowded with polymorphs; fibrin was absent. The epithelium of most of the bronchioles was completely desquamated, but the bronchi contained little secretion, thus confirming the macroscopical appearance of the dry cut surface of the lung and differing in this respect from the picture of a lobar pneumonia as commonly observed at necropsy on the fifth day of the disease. The microscopical appearances were practically those found when resolution of a pneumonic exudate is approaching completion, except that reparative changes in the bronchiolar epithelium were not yet apparent.[2]

The Blood Picture

A blood count on the morning of the third day of the illness showed 3,900 leucocytes per c.mm. and, later in the same day, before administration of serum, 6,000 per c.mm. On the morning of the fourth day the count was 9,000 per c.mm., and of the fifth 11,400 cells per c.mm., in each case before serum was given. The low cell count indicates a severe type of disease and failure of response on the part of the patient. The observed rise in the leucocyte count may be taken to indicate improvement. A sample of blood was collected post mortem, the serum separated, and the protective power estimated by mouse test. The patient's own pneumococcus was used; this was of maximum virulence, one ten-millionth of a cubic centimetre of a sixteen hours' blood-broth culture proving fatal to mice in forty hours. It is significant that the Type I antibody content of this serum was considerable, one-fifth of a cubic centimetre actually protecting mice against one thousand minimal lethal doses. The presence of so large a surplus of free antibody at this stage of pneumonia is, in our experience, clear evidence that the primary infective process has been overcome.

DISCUSSION

Gastric atony is a recognized complication both of lobar pneumonia and of acute abdominal disease and operation. Paresis, or even paralysis of the diaphragm, is apt to follow diaphragmatic pleurisy. Any or all of these factors may have contributed to the collapse of the lung. That the abdominal section had caused a severe disturbance of the autonomic nervous system was evident from the persistently rapid pulse uninfluenced by digitaline. The subsequent events are therefore easily understood.

The absence of consolidation of the left lung, which made complete collapse possible on the fifth day of the illness, is explicable on one hypothesis only—namely, that the antipneumococcal serum had entirely changed the normal sequence of intrapulmonary events. A state of fluid serous exudate into the pulmonary alveoli, characteristic of the second or third day of lobar pneumonia, must largely have persisted, instead of the comparatively static condition of solid hepatization proper to the fifth day. It seems probable that absorption of this fluid exudate must have been in rapid progress, and that the collapse of the lung, occurring over the period of about eight hours which preceded death, accelerated the expulsion of the inflammatory products.

Meanwhile, this remarkable case appears to us to afford unassailable evidence in favour of the use of concentrated antipneumococcal serum early in pneumonia. Had it not been for the unfortunate and purely accidental collapse of the lung, we are confident that our patient would have made a good recovery.

SUMMARY

The salient features of this case are as follows:

1. The onset exactly simulated an acute abdominal emergency.

2. The course of the case (excluding the unavoidable accident which caused death) illustrates the type of response to be anticipated from serum treatment of primary lobar pneumonia, due to the pneumococcal Types I and II, when exhibited early in the disease.

3. The pathological changes which successively follow in lobar pneumonia appear to have been profoundly modified by serum treatment, so that the normal process of inflammation has been curtailed and the disease process aborted.

4. The radiographic evidence and the careful study of physical signs prove beyond doubt that the lung was at one stage the seat of what is described as pneumonic consolidation. The findings post mortem show that the resolution of this process was almost complete by the fifth day of disease.

The observations recorded form part of an inquiry into the serum treatment of pneumonia undertaken by us for the Medical Research Council.

THE MODERN CONCEPTION OF EARLY PHTHISIS*

BY

H. V. MORLOCK, *M.C.*, M.D., M.R.C.P.

PHYSICIAN TO OUT-PATIENTS, VICTORIA PARK HOSPITAL; ASSISTANT PHYSICIAN TO THE MILLER AND THE HAMPSTEAD GENERAL HOSPITALS

(*With Special Plate*)

In order that I may make clear the new teaching, I shall first give a short summary of the old doctrine on this subject, which was that phthisis developed from a small discrete lesion situated just below the apex of the lung. The ulcer might heal to form an apical scar, or, on the other hand, might slowly progress to involve the surrounding lung tissue, and thus gradually spread the disease from apex to base. This orthodox view had its foundation among the pathologists, who, in thousands of necropsies on cases of pulmonary tuberculosis, found the oldest lesion in the apical region, with less intense involvement of the lower parts of the lung; further, they discovered an apical scar in 95 per cent. of patients who had not died from pulmonary tuberculosis. They therefore argued that in those cases in which pulmonary tuberculosis developed it most probably had its origin in the apical region, from which it spread downwards. The clinical interpretation placed on this teaching was that the first signs of pulmonary tuberculosis were usually found in the apical region, that the disease was of slow, insidious onset, and that it spread from apex to base. Further constitutional symptoms (pyrexia, anorexia, loss of weight, and lassitude) were often shown some considerable time before the disease process gave rise to physical signs in the chest. Therefore, in the diagnosis of the early case of phthisis, great stress was laid on the history of constitutional symptoms, and physical examination was concentrated on the apical regions. Doubts were first cast on this old teaching by statistical evidence when it was established in Germany that, in 1,438 cases[1] in which this apical lesion was diagnosed, only 7 per cent. developed phthisis; yet the death rate from this disease among the general population was 10 per cent. In other words, patients who were regarded as early cases of the disease did not develop the disease with any greater

* An address delivered to the general practitioners of Bermondsey.

frequency than the average population. This suggests that the apical scar is unlikely to be the starting point of phthisis.

A New Doctrine

The new teaching owes its conception to the work of Assmann,[2] Lydtin,[3] and, above all, to Redecher,[4] who examined series of skiagrams of tuberculous patients, and, by this means, was able to follow the course of the disease in some of his patients from the earliest manifestation. Beginning at the stage of initial or early infiltration, he was able to see in various patients the development of this condition into all the various forms of phthisis, previously described by the pathologists as originating in the discrete apical lesion. The new doctrine has thus been founded on radiological findings, while the old conclusions were deduced from the post-mortem room. As a broad principle, we may take it that we are less likely to fall into error by observing the course of a disease than by making deductions from the end-result seen at necropsy.

Redecher says that phthisis first develops as an acute infiltration of the lungs. This is shown on the skiagram as a definite soft shadow, the margins of which are not sharply defined. The lesion may develop in any part of the lung field, and it may vary in size from that of a cherry to that of an apple. The commonest site is the infraclavicular region, but frequently it occurs in the middle field, the basal field, and, now and then, at the apex. This initial infiltration (which is represented by a small area of broncho-pneumonia, surrounded by a perifocal inflammation) may occasionally heal with or without treatment, leaving only a scar; generally, if left without treatment, it spreads by one or more of the ways described below.

Method of Spread

The changes may occur in a very short time; it is not a matter of months, but a question of weeks at the most, possibly only days; once a spread has taken place, the disease becomes much more difficult to control.

1. The initial infiltration spreads by small aspiration broncho-pneumonic areas forming around the initial lesion.

2. Coincident with the aspiration spread, or occasionally before an aspiration spread has formed, the initial infiltration may undergo caseation, and cavity formation takes place. This latter process may occur in the short space of four or five weeks, or less.

3. While the initial infiltration still appears to be intact, there may appear in another part of the lung, or the other lung, a second infiltration—the so-called "daughter infiltration," which is probably an aspiration spread. The daughter infiltration may follow a course similar to that of the initial infiltration. If the aspiration process goes on increasing and unchecked, the condition becomes one of acute phthisis. If, however, the disease process is slowed down, a certain amount of fibrosis takes place; cavities already developed become thick-walled, the aspiration spreads show tendency to fibrotic changes, and the picture develops into one of chronic phthisis.

Clinical Features

If we accept the initial infiltration as the earliest manifestation of phthisis amenable to diagnosis (most clinicians in Germany have accepted it, and an increasing number in America and in this country are now doing so) we require to know how to recognize it clinically. In a typical case, the patient, usually a young previously healthy adolescent or adult, has a short, acute, febrile attack with indefinite symptoms. Perhaps a cough is present (often the patient will not consult a doctor at this stage). The acute pyrexial attack passes off in a few days; the patient feels himself again, and returns to work, but the cough continues. Sputum may be present, but as often as not is absent at this stage. If the patient is examined during the acute febrile attack, or shortly afterwards, the physical signs in the chest may be completely absent, or, if present, will be found over the infiltration. The latter is usually in the infraclavicular region, but may be in the axillary region or base, and consists of nothing more than a slight change in the percussion note, slight alteration in breath sounds, and the presence of post-tussic crepitation. If the lesion is near the surface, friction may be heard, and the patient will complain of pain.

It will be seen that these clinical manifestations, particularly in those cases without physical signs in the chest, are extremely likely to be regarded wrongly as "influenza," and it is a fact that many are at first diagnosed as such; the febrile period having ended, the patient is allowed to return to work, the cough persists, and constitutional signs make their appearance. By the time the disease is diagnosed, the initial infiltration has broken down to form a cavity, with or without an accompanying aspiration spread. The constitutional changes—loss of weight, lassitude, anorexia, night sweats—which have long been regarded as the earliest manifestations of this disease are in reality quite late symptoms.

Diagnosis

The important point which emerges is that if we are going to discover these cases at the earliest opportunity we must suspect every acute febrile illness without physical signs in a young adult as being due to pulmonary tuberculosis, except during the time of an influenza epidemic. Then only should we rest content with the diagnosis of such a clinical syndrome as influenza. The diagnosis of influenza, except during an epidemic, is usually a false one.

A matter which should always be inquired into is whether or not the patient has recently been in contact with a tuberculous person, not necessarily at home, but in the office or factory. My experience is the same as that of Redecher and others—namely, that a large percentage of patients with initial infiltration have been in contact with an open case. The absence of history of contact with a known source of infection does not negative the possibility of the disease.

In a number of cases the first symptom is a haemoptysis. In such the physical signs are often absent, but a skiagram shows the initial infiltration. In a few the acute febrile attack continues, the patient remains ill, and physical signs develop in a very short period. These cases are less likely to be overlooked. A few have given no history of illness, and have been discovered only when examined as a routine because they have been in contact with a known case. In many instances it is the *x* ray alone which gives the first evidence of active disease.

From what I have already said it must be clear that, in order to diagnose a case in the stage of the initial infiltration, we must never wait for constitutional symptoms to appear, but, in the young adult, we must regard with grave suspicion an occurrence of the symptoms described above, paying particular attention to the examination of the chest, not only in the apical region, but in the infraclavicular regions, in the axillae, and also the bases, and never omitting to search for post-tussic crepitations. Even if the examination of the chest is negative we should not be content, but if sputum is present we should have it examined repeatedly. If no sputum is present (as is often the case at first) a skiagram must be taken. Only when these examinations have been carried out and are negative should our suspicions be allayed. If we procrastinate, we may be losing the most valuable time for instituting therapy, because, in the course of a week or two, the infiltration may break down and cavitation may occur, or an aspiration spread may take

place into the other lung, or the lesion may reach the surface, causing a pleurisy and adhesion, which will seriously interfere with a subsequent artificial pneumothorax.

In the diagnosis of early phthisis, it is far better to have a negative sputum and a negative skiagram than a missed case. Radiology plays an important part in the diagnosis of the initial infiltration, but it is not the deciding factor, for the skiagram of this lesion may bear a close resemblance to a small pneumonic area, a lung abscess, a new growth, or a gumma. It is only by taking into account the clinical history, the physical signs or the absence of physical signs, the pathological examination of the sputum, and, sometimes, of the blood for leucocytosis or Wassermann reaction, that the *x*-ray picture can be correctly interpreted. The pathologist, the radiologist, and the physician, when united, are becoming more and more powerful in the field of diagnosis of pulmonary disease. It is to be remembered that this new teaching was established by a physician, working hand-in-hand with his radiological and pathological departments.

TREATMENT

There is no doubt that a certain number of these initial infiltrations will heal and become fibrotic if the patient is given general sanatorium treatment only; on the other hand, the majority of them tend to spread if so treated, and the difficulty is that in a given case it is not possible to say whether the patient will do well on general treatment only. I have seen these cases treated by rest alone; in the majority this line of treatment has been followed by a spread of the disease, and I have wished that artificial pneumothorax had been induced at the start. This is the best form of therapy, and the longer it is delayed the greater is the possibility of a spread taking place which may jeopardize the future artificial pneumothorax. At the same time it must be admitted that artificial pneumothorax does not arrest every case, particularly if cavitation has already occurred, but the sooner it is induced the greater is the chance of success. Because of the success of early artificial pneumothorax it is imperative to diagnose intact initial infiltration before cavitation or spread has taken place.

In my previous publication on this subject I translated Redecher's "Frühinfiltrate" as "early infiltration." Zimmerli and Simmonds,[5] in a recent paper, suggest that "initial infiltration" is a better term, because the infiltration is the initial lesion of phthisis rather than the earliest manifestation of pulmonary tuberculosis in its broadest sense, which must include such lesions as Ghon's primary focus and complex. In this paper I have adopted the term "initial infiltration."

The two skiagrams reproduced (Figs. 1 and 2, Special Plate) show the typical radiological appearance of the initial infiltration. My thanks are due to Dr. V. Sparkes for the skiagrams.

A CASE OF MULTIPLE OSTEOCHONDROMATA WITH OBSTRUCTED LABOUR

BY

E. J. BLACKABY, M.R.C.S., D.T.M. AND H.

DISTRICT MEDICAL OFFICER, NICOSIA, CYPRUS

(*With Special Plate*)

Bony tumours of the pelvis obstructing labour are rare, and it is uncommon to find multiple affections of this structure in the condition known as "multiple osteochondromata." The case described below is a combination of these two circumstances.

The patient was a woman of 28, well developed though of short stature (5 feet). She was married in 1928, and in the following year had a five months' miscarriage. On August 23rd, 1930, she was admitted to hospital in labour, which had been in progress for over twenty-four hours. She said that there had been slight loss of blood since the pains began, and that the membranes had ruptured. On admission her pains were frequent and strong.

On abdominal examination the lie was longitudinal, with the head above the pelvic brim. There was a definite overlap of the foetal occiput above the symphysis pubis, and the head was very freely movable between the pains. It was quite impossible to press the head down into the pelvis and to make it engage. The pubic bones seemed abnormal, but no definite opinion could be arrived at owing to the overlapping of the head. The foetal heart sounds could not be heard.

When the vagina was examined the os was fully dilated, and the presenting part was high and difficult to feel. No abnormality could be made out in the pelvic cavity. The pelvic measurements were: interspinous 9½ inches, intercristal 11 inches, and external conjugate 7¾ inches. After the vaginal examination was completed, a large bony tumour of irregular outline was noticed on the inner side of the right femur at its lower end. It felt like a large exostosis, and, according to the history, had been present since early childhood. A further examination of the bones showed similar, but smaller, masses on the opposite femur, the head and lower end of the right tibia, and the head of the left fibula. It seemed probable, therefore, that the abnormality felt on the pubic bones, preventing descent of the head, was a bony growth of similar nature. In spite of strong pains there was no advance of the foetal head, and a Caesarean section was considered the best method of delivery. This was accordingly performed, and the woman was delivered of a living and healthy male child, which weighed nine pounds. There followed an uncomplicated puerperium, and the patient was discharged from hospital on September 6th.

DESCRIPTION OF RADIOGRAMS

Radiograms taken afterwards are shown on the Special Plate. The pelvis (Fig. 1), besides showing growths of bone on its outer surface, exhibits a tumour of the superior ramus of each pubic bone on either side of the symphysis, narrowing the pelvic inlet and rendering it somewhat asymmetrical. This photograph also shows involvement of the upper ends of both femora by the disease. The right knee region (Fig. 2) shows multiple masses on the lower end of the femur and on the upper ends of the tibia and fibula. The left knee region presented similar but less extensive changes. These leg conditions caused no disability in walking. Screening of the upper limbs revealed osteochondromatous growths in the following situations: (1) upper end of the humerus on both sides; (2) upper end of the left radius; (3) distal end of the fifth metacarpal on the left hand.

TREATMENT

Treatment for so widespread a condition seemed impracticable, especially as it is said that these tumours do not grow after adult life is reached, but the patient was advised that a future pregnancy would necessitate another Caesarean delivery. The fact that she lives within easy distance of hospital influenced one against any attempt at sterilization by ligaturing and dividing the tubes at the time of operation.

COMMENTARY

This type of bone tumour starts as an enchondroma,[1] which ossifies later, near the extremities of the long bones of the limbs. According to Thompson and Miles,[2] it occurs neither in membrane bones nor in bones entirely formed from cartilage; this is borne out in this case. These authors mention involvement of the iliac crest, and Chaumet[3] also refers to a case in which a mass had formed on the anterior superior iliac spine, but no mention is made by them of the os pubis as a site. Roughly, as has been observed in other cases, there was a tendency to symmetry of the outgrowths in this particular patient. Heredity[4] is stated to play a part in the production of the condition. This patient's parents died "many years ago," and no cause of death is known. She has two brothers and a married sister, who is childless, but it was impossible to get them to come for examination; however, as far as can be ascertained, they have no deformity. The child was examined in November, 1930, and showed no signs of juxta-articular tumours.

My thanks are due to Dr. Coureas of Nicosia for taking the radiograms which are published as illustrations of this case.

THE HEALTH OF THE WORKER IN CHROMIUM PLATING

BY

HUBERT B. TRUMPER, B.A., B.CHIR.CANTAB.
MEDICAL OFFICER TO THE ASSOCIATION OF BRITISH CHROMIUM DEPOSITORS

Workers in this industry suffer disablement, usually temporary, from one or more of the following effects of exposure to chromic acid or its salts: (1) dermatitis; (2) ulceration of the hands, arms, or feet; (3) ulceration of the cartilaginous part of the septum of the nose; (4) vomiting after food.

The process of chromium plating consists in wiring the articles on to a frame ready for the plating vat, the actual plating, which lasts anything up to fifteen minutes, the unwiring, swilling, and polishing of the plated articles. A relatively large current is used in the plating tank, from 500 to 1,000 amperes and 4 to 10 volts. The solution contains 50 per cent. of chromic acid, and during the working of the tank reddish-brown *fumes rise* up into the air, to be sucked off by exhaust fans. Analysis reveals that these fumes contain upwards of 60 per cent. chromic acid, forced up in the form of a spray by the evolution of hydrogen at the cathode. The polishing of the work is done on a calico mop impregnated with either white or green "compo." The abrasive in the white compo is fused alumina; in the green it is a green chrome oxide (Cr_2O_3). Both these are held as a bond by high-class stearine. Here also the dust from the polishing is sucked off by exhaust fans. Employees actually working on the plating tanks are, as might be supposed, most liable to trouble, but any or all of the conditions mentioned above may occur at any stage of the plating process, or even in persons working in the same shop.

There are at least four main factors in the production of these conditions: first, a septic process in the body of the worker; secondly, inefficient exhaust apparatus; thirdly, a moisture-laden atmosphere, a sweat-laden skin, or both; and, finally, carelessness on the part of the operator.

PREVENTION OF DISABLEMENT

Persons to be employed in this industry should be medically examined before commencing on this process to prevent those with such obvious septic foci as foul teeth or tonsils from undertaking work which will inevitably lead to disablement. Sepsis of the nose, mouth, and pharynx is the commonest predisposing factor. The exhaust system of the tank should be sufficiently powerful to draw the smoke from the cigarette at the lips of a man standing by the tank. Scrupulous cleanliness on the part of the operator is, happily, as unnecessary as it is difficult to obtain. It is important, however, that wash basins, with a good supply of really dry towels, should be provided. In addition, the skin must be protected with some form of grease. This is of great assistance in preserving the health of the horn cells. The most satisfactory is a modified Lassar's paste with a preponderant base of pure vaseline. This should be smeared on the hands and arms before work is commenced, and a small piece inserted into each nostril, which quickly spreads over the exposed mucosa. In one large plant the operators use a specially prepared soap free of alkali and containing a proportion of free lanoline. This extra lanoline is left as a thin deposit on the skin after the hands and arms have been washed. Rubber gauntlets are compulsory, and are worn where contamination with the solution is inevitable. If they are worn continuously the additional perspiration produced more than counteracts the beneficial effect of the protection. Respirators are not of proved value. In a large plant the floor quickly becomes awash with drippings from the tanks and swills. This is a potent factor in the causation of trouble, and can be obviated by covering the floor with fresh sawdust each morning and sweeping clear at the conclusion of the day's work. Carelessness on the part of the operator can be avoided only by intelligent supervision.

TREATMENT

Dermatitis.—The usual positions for this form of dermatitis are the hands, arms, face, and occasionally the chest. The onset is sudden, but it is very unusual for an attack to occur until the operator has been in contact with the plating plant for at least six months. A severe case presents a horrifying appearance. The face is intensely red, and swollen out of all recognition. I have seen four cases in which oedema was so severe as to cause temporary blindness. Where the arms are affected they, too, are red and swollen, and the affected parts itch intensely, or may even be excruciatingly painful. The conjunctivae are injected, but the mucosa of the mouth seems to be unaffected, save that some patients complain of intense tingling of the tongue. At this stage the patient should be put to bed and the affected parts covered with lint soaked in double strength calamine lotion. The dressing should be changed frequently. Morphine is sometimes necessary to allay the irritation. Twenty-four hours later the oedema has subsided; and the affected skin is dusky in colour, with clusters of brick-red spots separated by crusted effusion from the contracting corium. The skin should now be scrubbed with gauze soaked in spirit, carefully dried, and swathed in lint plentifully spread with Lassar's paste. This procedure should be carried out twice daily. As soon as all irritation has ceased, usually in two days, the patient should resume work in the plating shop, being dressed by the first-aid official night and morning. The majority are clear of the dermatitis in a week. If patients remain

away from work until the cure is complete, they render themselves very liable to a recurrence on resuming work. When efficient treatment is lacking at the commencement of the attack the skin suffers permanent damage, and often becomes thin and papery after prolonged absence from work. In such cases recurrence is almost inevitable. The ultra-violet ray is of no use in the treatment of this condition.

Chromium Ulcers.—These ulcers may occur anywhere on the body, but are most common on the knuckles of the hands or the dorsum of the foot. They are always produced by an abrasion of the skin contaminated by chromic acid. They are circular in shape, with heaped-up edges, and a central clean-cut hole leading down to a base covered with exudate. These ulcers have a strong tendency to heal, but may penetrate very deeply, even to the bone. They vary in size from a match-head to a threepenny piece, but I have seen one the central hole of which would just take a half-crown. They are sterile, and the ulceration is due to a ferment, trypsin (Prosser-White). Although painless, they itch intolerably at night. The first essential in treatment is to splint the part. The splint must be maintained until the ulcer is completely healed. The ulcer should be cleaned out with gauze and dressed with equal parts of zinc oxide and vaseline. It takes about a week to heal if treated early.

Chromium Ulceration of the Nose.—This may be either anterior or posterior; where ulceration has once commenced, perforation is inevitable. First the area of the mucosa becomes pale and atrophic; later a greyish slough appears in the centre of the affected area. Usually such ulcers cause no inconvenience and are discovered accidentally, but the patient may complain of "whistling at night." Occasionally the ulceration completely destroys the cartilaginous part, and attacks the bony septum. The patient may have periodic moderate epistaxis, and a continued profuse discharge of pus from the nostrils. In these cases he should be put to bed, and the nostrils packed alternately daily with gauze soaked in flavine 1 in 1,000. The treatment may be necessary for several weeks.

Vomiting.—This is a rare manifestation of chromium trouble, and is always associated with dermatitis, though it does not occur in the acute stage of the inflammation. I have seen only four cases of vomiting in over a hundred patients suffering from the effects of chromic acid. Three of them were girls in a polishing shop, and one a man employed on a plating tank. The three girls were all very mild cases, and cleared up after being away from work for a week. The man was profoundly ill. In all four cases the signs and symptoms were identical. The vomiting was almost effortless, and happened immediately after taking food. It was preceded by profuse salivation. It occurred most violently after exertion, and increased in severity during the day. No signs could be elicited, and the abdomen was normal in every case. There was mild constipation. All the usual gastric sedatives were useless, and were, as a rule, returned within a few moments of swallowing.

THE PHARMACOLOGY OF CHROMIUM

It is probable that chromic acid is converted into chromous oxide when taken by the mouth, a part being deposited as such in various organs, and the balance being excreted in the urine. Ammonium sulphide precipitates from a solution of chromium compounds green chromic hydroxide; lead acetate solution precipitates solutions of chromium compounds in the form of a yellow lead chromate. I have never been able to demonstrate the presence of chromium compounds in the urine of any of my patients.

With a view to demonstrating the systemic effects from the exposure of the operator to chronic acid, four men were selected for examination. These men were all between 30 and 40 years of age, and all had worked continuously over a chromium plating tank for more than two years. A general clinical examination revealed a mild chronic catarrhal condition of the nose and throat in all the patients. One had a perforation of the septum of the nose of which he was ignorant. A complete blood examination showed a relative small lymphocytosis in all the patients, otherwise there was nothing abnormal. The day and night urine of each patient was tested, but failed to disclose the presence of chromium compounds. There was no albuminuria.

In spite of the fact that no evidence of absorption of chromium can be produced, it seems that a certain sensitization point is reached in the majority of patients, beyond which trouble ensues. Though a well-marked case of dermatitis or ulceration can definitely be recognized as due to chromium, I have been loath to use the term chromium poisoning, as all the conditions described above appear in a variety of other trades.

In a recent series of fifty cases, fifteen were women. This is a high proportion, as very few firms employ women on the most hazardous part of the process—namely, the plating tanks. Women are undoubtedly more susceptible to trouble.

The following table shows the number disabled from each condition, where the condition mentioned is the predominant factor.

Dermatitis	33
Ulceration of the nasal septum	4
Vomiting	4
Ulceration of the hands or feet	9
Total	50

None of these patients had received suitable first-aid treatment, with the result that their condition took a considerable period to clear up, the average time lost being nine weeks. Where adequate treatment and supervision are immediately available the average time lost is under a week.

The preventive measures outlined above are now being carried out by several large firms locally, and are proving successful. Prior to these methods being used there were always at least 10 per cent. of the personnel of the chromium plant suffering from one or other of these conditions. For the last three months there have been no cases in these works.

SUMMARY

1. Disablement among the operators on a chromium plating plant can be prevented.

2. The essentials of prevention are the elimination of septic foci and the protection of the skin by a film of ointment. The floors of the plating shop must be dry, and the exhaust apparatus efficient.

3. Persons suffering from any trouble due to chromic acid should have efficient first-aid treatment, and should cease work only in exceptional circumstances.

4. Women should not be employed except in the polishing shops.

5. There is no evidence of absorption of chromium by the workers in this industry.

I am indebted to Major A. J. Round, of B. J. Round and Sons, Birmingham, for his help in the prevention of disablement in this industry.

The soap and ointments mentioned above can be obtained in a satisfactory form from Philip Harris and Co. of Edmund Street, Birmingham.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

PROLONGED OBSTRUCTION OF LARGE BOWEL

In the following case of obstruction of the large bowel the noteworthy feature is the duration of the symptom, which continued on and off for fifteen months, and was at one time absolute for a period of fourteen weeks.

I first saw the patient, Mrs. L., aged 81, in April, 1929, when she presented symptoms of obstruction of the large bowel, due apparently to a faecal impaction. This readily yielded to enemata and a dose of castor oil. Gradually increasing difficulty in getting the bowels to move followed, and in July another attack of obstruction occurred. Nothing could be felt on palpation of the abdomen or on rectal examination.

The patient was seen by Mr. L. Fuller in consultation, and a gurgling noise constantly recurring in the splenic area suggested to us that it was a case of carcinoma of that portion of the colon. An operation was proposed if the obstruction remained absolute. However, a daily dose of calomel, enemata, and a diet leaving as little indigestible residue as possible, kept the patient up and about till April 11th, 1930, when again an attack of obstruction set in. Injections of pituitary with eserine and enemata this time failed to produce an action of the bowel. The patient seemed to realize she had a growth, and, with the concurrence of her family, refused operation.

From this date till her death on July 17th, fourteen weeks later, no action of the bowels occurred. During this time there was no faecal vomiting whatever, though on several occasions the contents of the stomach were rejected, on three occasions with haematemesis. There was very little pain, though constant rumblings continued over the abdomen. Distension was not marked till the last fortnight. The patient was fed now only on meat extracts, fruit juices, champagne, and water, ad lib. An albuminuria of some years' standing remained unaltered, and no trouble with the kidneys was experienced. The mind remained quite clear till the last two days, when she became comatose and died. No post-mortem examination was permitted.

Bath. O. COLVILLE, M.D.

A CASE OF DOUBLE GALL-BLADDER

The following case of two gall-bladders occurring in one person seems worthy of record, in view of the rarity of such a condition.

C. B., European female, aged 52, was admitted to Grey's Hospital, Pietermaritzburg, on July 24th, 1930, with a history of what seemed to have been an attack of biliary colic a few days previously; she said she had been subject for some years to flatulent dyspepsia. On examination, she presented marked tenderness in the gall-bladder region. Cholecystography showed a very poor filling of the gall-bladder, and the *x*-ray report suggested cholecystitis.

An operation was performed on August 1st, through a right paramedian incision. The stomach and duodenum were found to be normal. The gall-bladder was then examined, and appeared to be fairly normal, only a few small adhesions being present between it and the adjacent parts. However, in cases where symptoms and cholecystographic examination have pointed to the gall-bladder as the probable cause of trouble, it has been my experience that removal of that viscus is usually successful in relieving symptoms, even though its macroscopic appearance might be normal when seen at operation. I decided, therefore, to remove the gall-bladder in this case. The cystic artery ran along the median aspect of the cystic duct, and was ligatured. After ligature of the cystic duct, and during separation of the proximal part of the gall-bladder, I found that instead of the gall-bladder separating from the fissure of the liver in which it should lie, it was peeling off from what was at first taken for a diverticulum of itself, situated between it and the liver. I was able, however, to separate the gall-bladder completely from this other structure, which was then revealed as another gall-bladder lying above the first. The cystic duct of this second gall-bladder penetrated deeply into liver substance, and it was therefore not possible to trace the duct to its conclusion. I ligatured the duct, and removed the second gall-bladder, being fortunate enough to get both gall-bladders away intact. The appendix was then removed, and the incision closed, with drainage down to the stumps of the two cystic ducts.

The first gall-bladder was of about the average size; it contained normal bile and no gall-stones. The second gall-bladder was half the size of the other, the bile being much paler; it contained twenty-nine small gall-stones.

Recovery was satisfactory, and the patient left the hospital on September 6th.

W. H. HUGH CROUDACE, M.B.,
B.S.Durh.,
Honorary Surgeon, Grey's Hospital,
Pietermaritzburg, Natal.

PERSISTENCE OF THE COMPLETE WOLFFIAN DUCT

I had the good fortune on March 30th, 1930, to see and operate upon a case of such rarity as to be worthy of placing on record.

The patient, a female aged 6 months, was sent to the Royal Hampshire County Hospital at 10.30 p.m. The mother had called in her doctor on account of a round swelling, the size of a walnut, which she had noticed protruding from the vagina. The child had been fretful during the preceding twelve hours, and appeared to have severe abdominal pain, spasmodic in character. The bowels had been open during the day, and micturition had been normal. There was no previous history of any vaginal discharge. The temperature on admission was 101°, and the pulse rate 160. An examination under a general anaesthetic was carried out. An oval swelling, the size of a walnut, was found protruding from the vulva, in the centre of which was a necrotic patch. A probe was passed through this for a distance of about 2½ inches. In the right iliac fossa was a swelling which appeared to run backwards into the loin.

Operation

Under open ether anaesthesia, the abdomen was opened by a right paramedian incision, which ultimately extended from the pelvis to the costal margin. A fluctuating tumour was found lying behind the peritoneum, extending from the right lateral vaginal fornix, passing outwards in the base of the broad ligament to the lateral wall of the pelvis, and lying ventral to the right ureter, whose course it followed, to be lost in the cellular tissue at the upper pole of the right kidney. The peritoneum at the outer side of the caecum was incised, and the caecum and ascending colon retracted mesially. The tumour was separated with considerable difficulty from the right ureter, and detached first from the upper pole of the right kidney. The lower end was divided between clamps at the side of the bladder, and the tumour removed. Both ovaries showed multiple cysts, otherwise the pelvic organs were normal. The retroperitoneal tissue was drained through the lower end of the abdominal wound, and the abdomen rapidly closed as the child's condition gave cause for alarm. Forty-eight hours after the operation the child developed acute bronchitis; apart from this the convalescence was uninterrupted, and the patient is now well.

The tumour was a hollow viscus 5½ inches in length, the diameter varying from 1/2 to 1/4 inch, and was similar in appearance to a varicose vein. The microscopical report was as follows: "The walls are formed of fibrous tissue with round-celled infiltration; no epithelial cells were seen. The contents are pus, no organisms are to be recognized, and cultures are sterile after forty-eight hours' incubation."

Having referred to Grieg and Hertzfelt's exhaustive report on their two similar cases, I find little to add of interest. Their cases were of older children (aged 3 and

6 years), both of whom had had vaginal discharge of some considerable standing. Neither showed any vaginal swelling. However, both children were females, and in each case the tumour was on the right side. I think there is no doubt that the case now reported is an example of persistence of the complete Wolffian duct, with a superimposed infection of the contents.

Winchester. JAMES TROUP, M.B., F.R.C.S.Ed.

Reports of Societies

ACUTE INTESTINAL OBSTRUCTION

At a meeting of the Brighton and Sussex Medico-Chirurgical Society, held on April 4th, the president, Mr. H. NETHERSOLE FLETCHER, in the chair, Mr. J. R. H. TURTON read a paper on acute intestinal obstruction.

Mr. Turton began by giving statistics of 300 cases of acute obstruction admitted to the Royal Sussex County Hospital during the past ten years. Of these cases, 96 were due to obstruction from intra-abdominal causes, and 204 to strangulated internal hernia. The total mortality was 30.33 per cent. (52.1 per cent. for the intra-abdominal cases, and 20.1 per cent. for the hernias). The average age of the former group was 48.9, and of the latter 59.1 years. The duration of acute symptoms prior to hospital admission was 2 days 20.4 hours and 1 day 21.9 hours respectively. Highest mortality rates occurred in the cases of internal hernias, carcinoma of the colon, and multiple adhesions, while the lowest rates were found in the cases of obstruction caused by a single band or by impacted gall-stones. The average duration of acute symptoms before admission varied widely in the several classes of obstruction. The different mortality rates in the several classes could not be attributed to the different periods of delay in the diagnosis. Among the cases of strangulated hernia the mortality was 22 per cent. for the inguinal (91 cases), 12.2 per cent. for the femoral (90 cases), 43.75 per cent. for the umbilical (16 cases), and 42.85 per cent. for the ventral (7 cases). Attention was drawn to the low mortality among the femoral cases in the female (64 cases, with 4 deaths). Of these four cases, two were late ones, the hernia in each having been strangulated six days, necessitating resection of the bowel for gangrene; one was a case of toxic goitre, the patient dying suddenly three days after operation; the fourth was a case of chronic nephritis, death being caused by suppression of urine. Faeculent vomiting was present in 24 per cent. of the intra-abdominal cases, with a mortality of 56.5 per cent., and in 15.7 per cent. of the hernia cases, with a mortality of 50 per cent.

Mr. Turton briefly discussed experimental work bearing on the causation of death in intestinal obstruction, with special reference to the work of Williams on *B. welchii* toxaemia, and to the subject of chloride depletion. He dealt at greater length with early diagnosis, laying stress on the character of the pain, the presence of local tenderness, the value of auscultation, and the rectal examination. He made reference to Case's work on radiological examination, and to the more recent work of Rabwin and Carter in this field. In regard to the previous history, as elicited in the County Hospital cases, the speaker noted that, of the forty cases due to adhesions, twenty-one had undergone previous abdominal operation, and in all of these cases the obstructing agent was a clear result of the previous operation. He briefly discussed the question of treatment, urging the necessity for pre-operative preparation, especially in the matter of gastric lavage and saline infusions. In conclusion, he entered a plea for earlier diagnosis, and said that, in proof of the desperate nature of many cases on admission, 50 per cent. of the deaths in small intestine obstruction occurred within twenty-four hours of operation.

POPLITEAL ANEURYSM

At a meeting of the Section of Surgery of the Royal Academy of Medicine in Ireland, held on April 10th, with the president, Mr. R. ATKINSON STONEY, in the chair, Mr. SETON PRINGLE read notes on two cases of popliteal aneurysm, and exhibited one of the patients. Both cases occurred in elderly men with marked hardening of the arteries. In one the Wassermann reaction was positive, and in the other negative. In each case there was marked circulatory disturbance of the leg—oedema, engorgement of veins, and duskiness of the skin. One patient had gangrene of the tips of three toes. Severe pain was a marked feature in both. In the first case, by operation the femoral artery in Hunter's canal, enclosed in its sheath, was divided between two ligatures. In the second case, the lumen of the vessels was occluded by multiple ligatures and the sheath injected with alcohol. In both, the femoral vein was divided between ligatures. After the first few hours the condition of the circulation in the foot on the affected side did not give rise to any anxiety. Both aneurysms ceased pulsating immediately the ligatures were tied, rapidly hardening up, and gradually decreasing in size. The patients, fifteen and four months respectively after operation, were in good general health and able to get about.

The PRESIDENT commented on the fact that the veins had been tied as well as the arteries; it had been formerly taught that if the main artery and main vein were tied up together, gangrene was almost certain. This idea, however, later changed, as the result of experience with gunshot wounds during the war. Mr. W. PEARSON said he thought it was more difficult to get good results in cases of pathological aneurysm, such as described by Mr. Pringle, than in traumatic cases. He had a large experience of aneurysms during the war, and mentioned a case of subclavian aneurysm in which he obtained an excellent result by distal ligation. In this case the Wassermann reaction was strongly positive.

SPONTANEOUS RUPTURE OF SPLEEN

Mr. SETON PRINGLE also read notes on a case of spontaneous rupture of the spleen. He first called attention to the fact that spontaneous rupture of the pathological spleen was not a very rare occurrence, but that only eight cases of spontaneous rupture of the spleen, normal both macroscopically and microscopically, had been reported. He doubted whether spontaneous rupture ever took place in a perfectly normal spleen, quoting Susman as to the possibility of rupture occurring in a localized pathological area which became so disorganized with haemorrhage that it escaped detection afterwards. In the case reported, the rupture happened in a healthy man while he was riding around his farm; careful questioning could not elicit any history of even slight trauma. The patient was suddenly seized with very acute abdominal pain, slipped off his pony, and lay down in the field. He was found shortly afterwards in a collapsed condition, and was carried home. The clinical picture for the subsequent five days, during which he was treated at his own house by his medical attendant, was very confused. The degree of abdominal pain varied considerably, but at times was very severe, and was located variously in the right iliac fossa, left iliac fossa, right hypochondrium, and left loin. Vomiting occurred

once only, but considerable distension, somewhat relieved by enemata, was a constant feature. The temperature remained normal, and the pulse never rose above 90. On admission to hospital on the sixth day the pulse was still only 80. The abdomen was markedly distended, but not rigid. General abdominal tenderness was present, most marked in the right hypochondrium and right iliac fossa. Movable dullness was present in both flanks. It was thought that the patient had a minute duodenal perforation, leading to a gradually extending extravasation. At operation the abdomen was found to be full of blood, originating in a rupture of the spleen. The spleen was removed without difficulty, but the patient developed pneumonia, and died on the fourth day after operation.

INDUSTRIAL LIGHTING

Sir JOHN H. PARSONS, who presided at a lecture on industrial lighting, given at the Royal Society of Arts on April 15th, remarked on the fact that distribution of illumination appeared to be as important as intensity, and more difficult to manage. Completely indirect lighting, which cast no shadow, was admirable for some purposes and out of the question for others. Thus it found fitting employment in an engineer's drawing office and in an operating theatre, but for such a task as sewing black threads on black satin, as revealed in a test at the National Physical Laboratory, it was useless. The subject of illumination, Sir John Parsons continued, could not be considered by itself; it was linked up with the problem of vision, and the visual organ was one with which the physicist was apt to feel most impatient, because it was a photometric apparatus which was never stable in any circumstance. It had two receptive mechanisms which acted at different intensities of light, and interfered with each other at intermediate intensities. He pointed out the necessity for a liaison between those engaged in the physical, and those in the physiological, aspects of the problem—on the one hand, the illumination committee of the Department of Scientific and Industrial Research, and, on the other, the committee of the Medical Research Council which concerned itself with vision.

The lecturer, Mr. D. R. WILSON, Deputy Chief Inspector of Factories, addressed himself for the most part to the good effects which satisfactory lighting had been found to produce. It was an important factor in safety. Industrial accidents due to falling or stumbling showed a clearly marked seasonal variation, the rate being highest in winter and lowest in summer; it was difficult to ascribe this to any other cause than inferior artificial lighting conditions as compared with daylight. Good lighting was also an important aid to production, as regards both quality and quantity. In printing, the output in the composing room had been found to increase, and errors to decrease, almost in proportion to the illumination provided. Finally, good lighting had a definite psychological effect on the worker, in that it made his environment more cheerful, cleanly, and orderly.

Mr. J H FISHER, in the ensuing discussion, said that under unfavourable conditions of illumination workers became unduly tired and depressed, and their output was materially reduced, but how far this was due to eyestrain and how far to other conditions affecting health was very difficult to determine. A general point made in the discussion was that while the conditions of illumination in factories might approach the ideal, the result was apt to be frustrated by the way in which the workers used their eyes in their off-time, reading close print under poor illumination, or, at the "pictures," watching movement in bright light surrounded by gloom. On the other hand, it was felt that the scientific study now given to factory illumination might result in conditions so obviously adequate and comfortable that workers themselves would insist on some approximation of their domestic and recreational conditions to the same standard.

Reviews

DISEASES OF THE TONGUE

It speaks clearly for the essential soundness of a surgical textbook that after the lapse of an entire generation it should be capable of such successful rejuvenation as to bid once more for first place among its kind. There comes a time, it is true, when the reader of the latest version of Butlin's *Diseases of the Tongue*,[1] is inevitably reminded of Captain Brassbound, who, at a critical stage in his career, was described as "churchwarden from the waist down, and the rest pirate." Nevertheless, the grafting of Mr. STANFORD CADE'S enthusiasm and very exceptional experience of radium on to the virile stock of Mr. W. G. SPENCER'S erudition and encyclopaedic knowledge of diseases of the tongue, has resulted in a healthy and fertile production that should be of great value to all into whose hands it falls.

Those familiar with the second edition (1900) will remember that its pages were devoted not only to the tongue, but also to the mouth and salivary glands, and to-day we find all the sections expanded, with new information, better set out and illustrated, and with bibliographies after each article or section. Of course, even now the last word cannot yet be said—for example, though many pages are devoted to leucoplakia, the account remains vague and uncertain. It must be admitted, with regret, that the senior author's style is not calculated to clarify the obscure. What does this sentence mean? "The influence of syphilis although latent, in the lesions just mentioned, when irritated may at a later period become cancerous ulcers." There are many like it. For instance, "Failure in use of the tongue is out of proportion to any simultaneous cause of paralysis." The paragraph on evolutionary wounds, with which the book opens, is very difficult to understand. The same may be said of paragraph M, page 304, on sarcoma. Does the sentence "Excoriations, traumatic ulcers, benign growths develop into different types of carcinoma" (page 359) mean quite what it says, or is the intention of the author merely frustrated by his use of words? Is the clinical sign of induration produced by "increased vascularity"? Does syphilitic leucoplakia "generally persist until cancer develops"? What constitutes the "translucent line of the basement membrane"? In passing—for we cannot refer to all the items in this comprehensive survey of disorders of the mouth and tongue—we note that in respect of the radium treatment of actinomycosis, the authors hint that beta therapy is perhaps more valuable than pure gamma.

The new, as distinct from the revivified, section of the book is that devoted to the radium treatment of cancer, and it must prove of the highest value to all surgeons. Operation by the knife has passed away: the triumphs celebrated in 1900 are now virtually relegated to the historical chapter. If radium cannot cure the early primary lesion more certainly than the knife, at least it does so without mutilation; and, in addition, "inoperability" is a term without meaning so far as radium is concerned. Not that every case proves susceptible even when treated—far from it; not that the technique of application is as yet perfected—nobody claims that; but even where radium still calls for help it appeals not to the scalpel but to the diathermy needle and loop, which here receive due attention. The presentment of this part of the subject is admirable. The directions for detailed treatment are lucid and sufficiently dogmatic; the difficulties,

[1] *Diseases of the Tongue*. By Walter G. Spencer, M.S., F.R.C.S., and Stanford Cade, F.R.C.S. Being the third edition of Butlin's "Diseases of the Tongue." London: H. K. Lewis and Co., Ltd. 1931. (Pp. xvi + 561; 123 figures, 20 plates. 35s. net.)

dangers, and disappointments are adequately emphasized; and the very difficult question of treatment of the glandular areas is judicially dealt with, as will be admitted even by those who do not agree on all points. Perhaps, in view of the rapid progress made in the last five years, not quite enough is allowed to the possibilities of radon, which may make up for its inconstant intensity by greater exactitude of distribution, greater facility of introduction, and therefore homogeneity of field. Moreover, some schools do not agree that surface or cavity application, in the treatment of cancer of parts of the tongue and floor of the mouth, "has no place." Some at least feel that the injury, however slight, done by implantation should be avoided, since even perfect cure of the primary lesion is so often followed by death from dissemination; and at least nothing should be done to promote it. Unfortunately, teletherapy has so far not proved its efficacy.

It is right that at this stage of a new method a monograph should be documented, and the 217 case reports at the end of the volume therefore amply earn inclusion. A treatise of this sort is not the place for any summary of modern research into the nature of the cancerous process or its causes, but the reaction of cancer to radium has concentrated attention on the histology of various forms of squamous-celled carcinoma, and that is fully reflected here, both in the text and in the excellent photomicrographs. It is a matter for speculation whether the wish, engendered by difficulties in the treatment of established cancer, is not sometimes father to the thought of a good many conditions as "precancerous."

An admirable book that must be read by all who treat cancer of the tongue; and there can be few, if any, among them who will not find instruction also in the pages devoted to non-cancerous disorders.

TREATMENT OF SCHIZOPHRENIA

Dr. LELAND E. HINSIE, Professor of Clinical Psychiatry, Columbia University, has written a monograph on the *Treatment of Schizophrenia*,[2] in which he suggests that a modified form of psychoanalytic technique may be used with advantage in certain cases showing early but definite schizophrenic symptoms. It is not claimed that psychotherapy is capable of converting the patient into a completely adjusted personality, and most psychiatrists will probably accept the view of the author, that in schizophrenia we have a constitutional emotional inferiority —"a deficiency of the original stock of libidinous capacities"—which imposes a limit to therapeutic efforts. Both clinical impressions and biological studies suggest that there is, in this disorder, not merely a deviation of the instinctive urges, but rather an inherent inadequacy which limits the patient's capacity for meeting the demands of life. It has, indeed, been the policy of the author to attempt the rehabilitation of his schizophrenic cases on the assumption that there exists this inferior affective capacity, as he has found this to be a helpful attitude from the practical standpoint. It will, for instance, prevent the physician from suggesting marriage to a schizophrenic patient who has been cured of his symptoms; he will realize that attempts at adult sexual life in marriage in such an individual would be very likely to precipitate a breakdown, even though the treatment may have been instrumental in detaching the libido from symptoms, and be thus free to stimulate sublimated forms of social activity.

From the foregoing it will be seen that Dr. Hinsie's views on the nature of the type of reactions which he discusses do not differ from those held by the majority of psychiatrists. The essential interest of the monograph resides in the fact that he believes prolonged psychotherapy to be capable of dissipating the symptoms manifested in a certain proportion of cases. Such views merit attention, especially at a time when efforts are being made to organize treatment for the incipient psychoses before institutional care becomes necessary. It is interesting to note that the patients selected for treatment were nearly all dealt with in the out-patient department of a general hospital. In the development of this theme the author discusses the diagnosis of incipient schizophrenia, and also describes in detail the type of case he considers suitable for intensive psychological treatment. The treatment of more advanced cases, psychiatric social service, and occupational therapy are made the subject of discussion, and the concluding chapters give a summary of the literature on the treatment of schizophrenia. The book is written with sincerity and restraint, and the psychiatrist will find it helpful, informative, and encouraging.

SURGICAL EMERGENCIES

Surgical Emergencies in Practice,[3] by Messrs. W. H. C. ROMANIS and P. H. MITCHINER, was written, we are told in the preface, at the suggestion of several general practitioners who have not the time to wade through the pathology and alternative methods presented in a textbook. There must have been also a keen desire on the part of the authors to write such a book, as is shown in the crisp style and excellent presentation of surgical procedure.

The first chapter deals in a helpful way with some general conditions, such as shock and collapse, and with improvisations in a private house. We regret to note, however, that intravenous saline is damned with faint praise, because this is a procedure easily undertaken by the general practitioner, and often helps in an emergency until a blood transfusion can be performed. In the case of blood transfusion the use of Kimpton's tube might well be omitted, and we think the authors advocate too high a percentage of citrate in the commoner method. The section on fractures, dislocations, and sprains is very full, and here the practitioner will find clearly expressed views on the treatment of those conditions which in general practice are the commonest emergencies, and which cause the greatest anxiety. In the case of fractures of the phalanx, metacarpus, and carpus, the average duration of the disability at St. Thomas's fracture clinic is given, and this might be done in the other groups as well. The very clear account of emergency surgery of the brain, skull, and spinal cord, correlates the pathological with the clinical signs, and gives sound advice on treatment. It is doubtful, however, if the peripheral nerve injuries as described come under the heading of emergency surgery, and most of the illustrations are those of a long-standing lesion. The section on the respiratory system and lungs gives detailed descriptions of the emergencies encountered in this region, and we are glad to see that the authors advocate a tracheotomy after dividing the isthmus of the thyroid, instead of pressing the classical high and low method. The section on acute abdominal diseases is the best part of the book; it is written in a most readable way, and the reasons for the various procedures are put forward in such a manner as almost to convert one holding contrary views. For strangulated femoral hernia the authors presumably perform the old operation below Poupart's ligament; this, we feel, is not worthy of them. In the last chapter, on the genito-urinary system, the standard of the rest of the book is well maintained.

[3] *Surgical Emergencies in Practice.* By W. H. C. Romanis, M.B., M.Ch., F.R.C.S., F.R.S.Ed., and Philip H. Mitchiner, M.D., M.S., F.R.C.S. Churchill's Empire Series. London: J. and A. Churchill. 1931. (Pp. vii + 608; 158 figures. 18s. net.)

There are numerous illustrations, which are well done. Although repetition in the text is unavoidable here and there, it is surely not necessary to duplicate drawings showing a dropped wrist (pages 36 and 343), and the treatment of a mallet finger (pages 42 and 225). Some of the illustrations seem to be far removed from emergency practice, such as those on pages 232 and 233. But this is a small matter, and the book is a good one.

MONOGRAPHS ON OBSTETRICS AND GYNAECOLOGY

We have received from the publishers, Messrs. D. Appleton and Company, a complete set of the new edition of their series of *Gynecological and Obstetrical Monographs*.[4] These volumes, sixteen in number (including a composite index volume) are uniform in size and typography, and most of them are freely illustrated. All have been revised in the light of experience gained in the past ten years.

The first of the series presents a discussion on sterility and conception, by Dr. Charles Gardner Child, jun., of New York. The second, by Dr. Emil Novak of Baltimore, deals clearly and fully with menstruation and its disorders. The third is a treatise on symptoms in gynaecology, their etiology and interpretation, with notes on diagnosis, by Dr. Isidor Clinton Rubin of New York. The fourth is a clinical study of the complications of pregnancy, by Dr. Edward P. Davis of Philadelphia. In the fifth volume Dr. George William Kosmak of New York describes and discusses the toxaemias of pregnancy. The sixth, comprising an admirable account of birth injuries of the child, by Dr. Hugo Ehrenfest of St. Louis, has also been issued separately in a different binding by the same publishers at the price of 25s.; the first edition was noticed in a leading article in our issue of November 24th, 1923. The subject of the seventh volume is extrauterine pregnancy, and its author is Dr. Edward Armin Schumann of Philadelphia. The eighth, by Professor Franklin S. Newell of Boston, deals with Caesarean section, its indications, contra-indications, and technique. The ninth is a comprehensive essay on the subject of pelvic inflammations in women, their pathology, symptomatology, and treatment, by Professor John Osborn Polak of Brooklyn. The tenth gives a critical survey of pelvic neoplasms, by Professor Frank Worthington Lynch and Dr. Alice F. Maxwell of the University of California. In the eleventh volume Professor Charles C. Norris of Philadelphia studies those forms of tuberculosis which especially concern the gynaecologist and obstetrician. The twelfth is devoted to gynaecological and obstetrical pathology, with chapters on the normal histology and the physiology of the female genital tract and the peritoneum; the author is Dr. Robert Tilden Frank of New York. The thirteenth, on diseases of the vulva (a subject on the borderland between dermatology and gynaecology), is from the pen of Professor Frederick Joseph Taussig of St. Louis. The fourteenth, by Professor George Gellhorn of St. Louis, covers a wide field of non-operative treatment in gynaecology, and includes a chapter on radiation treatment by Dr. Henry Schmitz of Chicago. The fifteenth volume, on the surgery of the female pelvis, is by Dr. Carey Culbertson of Chicago, whose purpose is to present the technique of operative gynaecology, and to elaborate the indications for the procedures described.

As will be seen from our brief enumeration of subjects and authors, these fifteen practical treatises, by teachers of recognized standing in the United States, embrace a large part, but not the whole, of obstetrics and gynaecology. Each author has his own method of approach, and writes independently, from his personal experience and study of the literature. There is no general editorial introduction, and each number of the series must be regarded as standing by itself without relation to the others. It is thus a collection of monographs, not a system. As such it deserves the attention of all workers in this branch of medical practice.

[4] *Gynecological and Obstetrical Monographs*. Second edition. New York and London: D. Appleton and Co. 1931. (£13 13s. the set.)

RESPIRATORY DISEASE IN CHILDHOOD

The two volumes entitled Diseases of the Respiratory System[5] form part of a series of clinical studies in children by Professor P. NOBÉCOURT of Paris, which have appeared from time to time during the last five years. In a preface to the first of these volumes the author explains the object of these clinical studies, which is to supplement the systematic exposition of the subject as contained in the ordinary medical textbook. Professor Nobécourt has already written his own textbook, *Précis de Médecine des Enfants*, now in its fifth edition, and he has also completed six volumes of clinical studies, so that he has achieved an unusually complete presentation of the subject on which he is a recognized authority, both as writer and as teacher.

Respiratory disease plays an important part in medical practice among children, and these two volumes contain forty clinical lectures. The basis of each lecture is the presentation of one or more cases of respiratory disease which illustrate some particular aspect of the subject—pathological, clinical, or therapeutic. In addition to the clinical records, there is in each chapter an introduction, which brings into focus the special problem which the cases illustrate, and a commentary which adjusts this problem to the whole subject. Clinical charts, photographs, and radiographs, are also added. The two volumes thus form a clinical library and commentary of cases of respiratory disease in children. The kind of case selected for discussion is usually atypical or uncommon, or presenting difficulty in diagnosis or calling for modification in treatment. Another valuable feature is the inclusion of the respiratory complications of the infectious diseases. For example, cases are described of rhinitis in scarlet fever, of the forms of laryngitis complicating measles, of broncho-pneumonia in whooping-cough, and of the pulmonary complications of typhoid fever. It is an obvious advantage to have these conditions described alongside the non-infectious respiratory diseases, and, from the point of view of teaching, it enlarges the experience of the physician who has medical charge of all these conditions in one hospital. Tracheo-bronchial glandular enlargement is a clinical condition which has been particularly studied in France, and in these volumes there are several chapters dealing with this, not only with tuberculous mediastinal glands, but with what may be called idiopathic cases and those complicating any form of tracheitis and bronchitis, and with the rare examples of syphilitic adenitis. Types of sero-fibrinous and purulent pleural effusion are presented in no fewer than nine chapters, including streptococcal empyema, pyo-pneumothorax, and localized empyema of the apex and anterior thorax. There are several chapters on bronchiectasis, both in the early stage in cases of chronic broncho-pneumonia and in the fibroid lung of old standing. Tuberculous disease of the lung in children is dealt with in some of its important aspects—its early diagnosis, the evolution of the disease in the lungs, its association with whooping-cough, and the clinical features of miliary tuberculosis.

[5] *Clinique Médicale des Enfants: Affections de l'Appareil Respiratoire*. Par P. Nobécourt. Deuxième édition. Paris: Masson et Cie. 1930. (Première Série, pp. xvi + 362; 52 figures. 50 fr.; Deuxième Série, pp. viii + 479; 227 figures. 60 fr.)

This list of subjects dealt with is not a complete catalogue of the contents of the volumes, but it indicates the variety and the extent of the ground covered. Such clinical studies are a valuable contribution to medical literature; they are supplementary to the textbook, correcting and amplifying it; they form the foundation of clinical experience from which textbooks are written and revised. They also show British practitioners and teachers of the subject the methods of clinical examination and of clinical teaching in the medical schools of Paris. In clinical examination these lectures have the great tradition of Laennec, and in exposition they have that Latin brevity and clearness which distinguishes the medical literature of France. Professor Nobécourt's reputation as a teacher has attracted many British and American graduates to his wards at the Hôpital des Enfants Malades in Paris. He has done a great service to the medical profession in France, and beyond it, by putting on record his admirable lectures at the bedside, and thus placing at the disposal of many more his great clinical experience as a physician and his admirable gifts as a teacher.

NOTES ON BOOKS

A third edition of MACKIE and MCCARTNEY'S *Introduction to Practical Bacteriology*[6] follows only a few years after its predecessor, and is certain to maintain its popularity. It has been thoroughly revised and brought up to date, both by the introduction of new matter and by the omission of some less important passages. The attitude throughout is a practical one, and the book has the merits of brevity and sufficiency. Such subjects as the handling of the microscope, the preparation of media, serological tests, and the bacteriological examination of milk and water are shortly, yet adequately, described. A thoughtful feature is the relegation of some of the more advanced details to small print, so that the volume keeps its handy size. Indeed, the skill with which the essentials of bacteriology are presented within the compass of some four hundred small pages is remarkable. Illustrations depicting micro-organisms are not included, no doubt advisedly, since some practical acquaintance with them by experience or demonstration is to be assumed on the part of the reader. The student of bacteriology will find this small book most useful as an introduction and also for purposes of reference.

In *Petites Cliniques*[7] Dr. LOUIS RAMOND, physician to the Laennec Hospital in Paris, republishes from *La Presse Médicale* thirty-six clinical demonstrations given in the course of his hospital teaching. They cover a wide field, the largest number being on the digestive system, but are all attractive. The plan of representation is first a sketch of the patient's history, then a discussion of the diagnosis, followed by the prognosis and the appropriate treatment. The success of this method is well seen in these clinics—for example, that on a case of facial paralysis due to zona, on encysted hydropneumothorax, and on jaundice in secondary syphilis.

Studies of the mosquito, the house-fly, and the tapeworm have been incorporated in the second edition of Dr. L. A. BORRADAILE'S *Elementary Zoology*.[8] This well-illustrated textbook, which was reviewed in our issue of July 5th, 1924, can be recommended to medical students for its clear and concise exposition.

An ingenious infant feeding table,[9] with cardboard holder, has been devised by Dr. J. v. LUKÁCS and Dr. ALB. MEYERSTEIN as a sort of ready reckoner for workers who have frequently to struggle with the mental arithmetic necessary in this branch of medicine. By means of this, four chief questions can be answered at a glance—namely: How many calories does the infant require? How many grams of selected food must be given? How many calories are contained in a definite quantity of the selected food? and What will be the energy quotient for the child with a determined quantity of the selected food? For the increasing number of paediatricians in this country who use the metric system this table will be found most useful, and it might perhaps serve as a basis for the preparation of a similar table for English weights and measures.

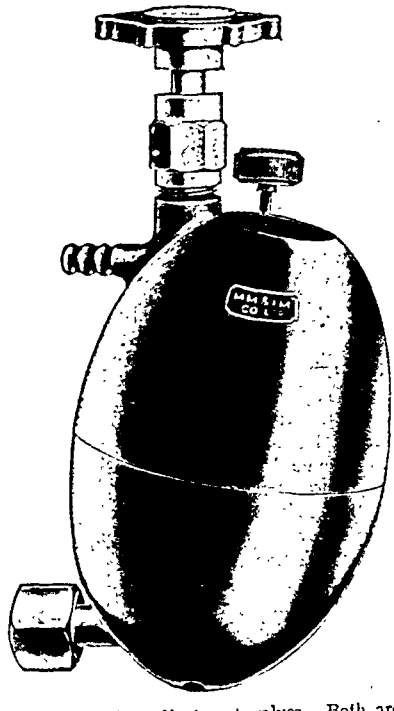
PREPARATIONS AND APPLIANCES

ADJUSTMENT VALVES FOR N_2O CYLINDERS

Dr. K. B. PINSON (anaesthetist, Manchester Royal Infirmary) writes: Finding, as doubtless many others do, the need for a valve which would enable a steady flow to be obtained from cylinders of condensed nitrous oxide gas, I



have designed two fine-adjustment valves. Both are simple, as distinct from pressure-reducing valves, and give a positive shut-off, which can be relied upon to prevent leaks, which I feel are responsible, in complicated apparatus, for much useless consumption of gas. One adjustment valve has fins cast on

the body, and the other has a large hopper for hot water, in one piece with the valve, and is, I have found, invaluable for intratracheal work. The illustrations are from blocks belonging to the makers, The Manchester Machine and Instrument Manufacturing Co., Ltd., 2, Booth Street, Manchester.

British Medical Journal

SATURDAY, APRIL 25th, 1931

THE STRUGGLE FOR HEALTH

In his latest book, *The Inborn Factors in Disease*,[1] Sir Archibald Garrod discusses the mysteries of human predisposition to disease. He recalls that health is a state only maintained by a continuous struggle against unhealthy influences. Man may be regarded as a complex organism striving to survive in the midst of a complex set of external agents. All through life we are assailed by bacteria and protozoa: we are the playthings of climate and the thralls of our food supplies. If our tissues are not first class and assembled with precision they show premature signs of wear and tear. Garrod's thesis is that in every malady there are two sets of factors at work—namely, internal or constitutional factors inherent in the sufferer, and external ones that fire the train. But disease is not a separate entity by which the body is possessed and damaged; it consists, as Thomas Watson observed, "in some derangement, suspension, or perversion of the continuous, normal, nutritive mutation and renewal of the bodily tissues."

The modern trend of medicine seems almost to have ignored the constitutional or inborn factors in the production of disease, because, perhaps, the great advances made during the last half-century have been chiefly in the fields of preventive medicine and aseptic surgery. In these branches of medicine attention is focused on sheltering the individual from external attack, so that his powers of resistance are not called upon. Garrod reminds us that there are constitutional tendencies, either inherited or acquired, which are powerful allies on one side or the other in the struggle for health. Shelter from attack will not free us from all the ills that man's body is heir to. Even in infective diseases the soil plays its part as well as the seed, and it is with the soil that this essay deals. "I know the families that have a way of living through everything, and I know the other set that have the trick of dying without any kind of reason for it," said the old doctor in Oliver Wendell Holmes's story. "Wittingly or unwittingly," says Garrod, "the practitioner of medicine is constantly engaged in the study of constitutions and predispositions." Patients have appreciated this better, perhaps, than the medical profession; they trust the family doctor because, as they say, he knows their constitutions. With the coming of bacteriology attention became concentrated upon the seed rather than on the soil; bedside observations seemed to be of less account than laboratory investigations. But the inborn factors, the diathesis, constitution, or predisposition—call them what we will—must be studied at the bedside. Internal factors determine the existence of natural liability to, as well as natural immunity against, infective diseases. Our power to resist bacterial invaders depends on protective mechanisms that have been evolved, some to destroy the invaders, and others to render their toxins innocuous. Sometimes the protective antibodies have been formed as the result of a previous invasion, in other instances the immunity is natural, inborn, and possibly inherited. Just as there are natural immunities, so there are natural liabilities, and these, like our individuality, have probably a chemical basis. Some day the antitoxins and their congeners will, Garrod expects, be isolated as pure substances, just as adrenaline and thyroxine have been isolated and synthesized. Not all maladies have their origin outside the body, or are due to invasion by bacterium, protozoon, or virus. Each of us is exposed every day to other unhealthy influences, against which we may or may not possess some inborn capacity of resistance. Many of us possess latent defects of structure or function, inborn, and for the most part inherited, which render us vulnerable by influences innocuous to the average man. Garrod quotes as examples the possibility of abnormal mesenteries of the caecum or colon leading to intussusception or volvulus, and the case of a woman dying in a uraemic convulsion, due to pressure of an enlarging uterus upon a single small kidney. Even in deficiency diseases there are personal variations indicating that some individuals possess tissues which can withstand vitamin shortage better than others. In haemophilia the inborn factor appears all-important, probably the absence of some enzyme concerned with blood coagulation, yet the subject of this anomaly may go through life unaware of it unless some external influences provoke its manifestation.

The symptoms attributable to disturbances of endocrine gland function provide striking illustrations of the inborn or constitutional factors in disease. It is easy to multiply examples of chemical or physico-chemical defects which contribute to a state of disease. There are also the strange tissue defects which Gowers named "abiotrophies," affecting chiefly the neuro-muscular system and causing the tissues to wear out prematurely. When we read Garrod's chapters on "Errors in metabolism" we begin to realize how vast a claim he is pegging out for inborn factors in the field of etiology. He considers the subject under three headings: (1) errors of metabolism which can be detected and studied by methods employed in the chemical laboratory; (2) inborn predispositions to, and defences against, particular infective maladies; (3) allergies, or the so-called idiosyncrasies. Of the first group gout is one of the commonest examples. The inborn error which predisposes to gout must be widely spread, but changes in diet and mode of life have rendered the exciting causes of the manifestations of gout less prevalent. Although we see less gout there has probably been no decrease in the number of potentially gouty persons in the community. But, so far, the inborn factor which

[1] *The Inborn Factors in Disease*. By Archibald E. Garrod, K.C.M.G., D.M., LL.D., F.R.C.P., F.R.S. Oxford: The Clarendon Press; London: Milford, Oxford University Press. 1931. (7s. 6d. net.)

predisposes a person to gout is unknown. Albinism almost certainly results from a lack of a melanin-producing enzyme. Congenital porphyrinuria is associated with a peculiar sensitivity to light. If the more pronounced departures from the average chemical type have such conspicuous effects, minor departures may play important if less conspicuous parts as inborn factors in disease. The protective substances known as antitoxins, agglutinins, opsonins, and the like, of which as yet we know nothing save the properties from which they derive their names, are undoubtedly chemical compounds which will presently be identified. Allergies and idiosyncrasies may appear to be the most elusive of all causes of disease, and in them the inborn factors are overwhelmingly important. But the researches of Lewis and Dale point to a chemical or physical interplay between antigen and antibody in the cells of the subject which results in liberation of histamine from the cells, causing the wheal, flare, or flush.

The author sums the matter up by saying that "to our chemical individualities are due our chemical merits as well as our shortcomings, and it is very nearly true to say that the factors which confer upon us our predispositions to, and immunities from, the various mishaps which are spoken of as diseases, are inherent in our very chemical structure, and even in the molecular groupings which confer upon us our individualities, and which went to the making of the chromosomes from which we sprang." He feels that it is in the ward rather than in the laboratory that the importance of inborn factors is to be appreciated. But unquestionably the laboratory must come to the ward if we are to solve the secrets of the inborn factors and explain aright the chemical basis of our infinitely variable individualities. The art of medicine has from earliest times made each of the other arts and sciences her handmaid by turns. It is to chemistry and physics that she looks at present. Sir Archibald Garrod was one of the first physicians in England to realize and teach this important truth.

POST-ENCEPHALITIS AND ITS PROBLEMS

There are still many difficulties about epidemic encephalitis which beset those specially interested in its etiology, and those who are clinically concerned with the diagnosis and treatment of the disease in its acute stage. Moreover, the fact that in many patients the disease pursues a chronic course, involving considerable disablement or demoralization, has created administrative difficulties also for those responsible for the care and after-treatment of these unfortunates. To a limited extent epidemic encephalitis has become a social problem. The prominence which was given to the troublesome, freakish, and even dangerous behaviour displayed by certain types of post-encephalitis subjects tended at first to focus attention rather on the interests of the community than on those of the individual patient. The troublesome juvenile who had become an intolerable nuisance in his own domestic circle proved to be equally undesirable in various schools and institutions for the backward or the wayward, as the case might be; his, or her, presence was found to have a demoralizing effect, both on the discipline of the institution and on the behaviour of the other inmates. And, until the passing of the Mental Deficiency Act of 1927, with its amended definition of "moral defectives," the resources of certified institutions were hardly applicable. At one time, indeed, a greater number of troublesome patients, by reason of their misdemeanours, were committed to penal establishments than were admitted to mental defective institutions. Attention then became re-directed towards the patient rather than towards the public. Among the praiseworthy pioneers in the movement that followed for providing special facilities for the accommodation and study of post-encephalitis patients were certain boards of guardians and the London County Council. From the first, a considerable proportion of poor patients of all ages suffering from chronic encephalitis have found ultimate refuge and relief in Poor Law institutions, but in 1925 certain Poor Law authorities undertook further responsibilities. Thus, early in 1925 the guardians of the poor of the city and county of Bristol set aside six beds in their institution at Southmead for the treatment and care of children suffering from the after-effects of encephalitis lethargica. In the same year the Metropolitan Asylums Board opened, at the Northern Hospital, at Winchmore Hill, an experimental unit, consisting of 100 beds, for the observation and treatment of children between 3 and 16 years of age suffering from post-encephalitis. Later, the Mental Hospitals Committee of the L.C.C. adopted the policy of concentrating in two closely adjoining institutions at Epsom—West Park and the Manor—the London post-encephalitis cases dealt with under the Lunacy Act or the Mental Deficiency Acts.

Concerning the work undertaken and the results achieved at Winchmore Hill and at Epsom, reports by Dr. G. A. Borthwick and Dr. F. L. Golla respectively, together with a foreword by Dr. F. N. Kay Menzies, have been published lately by the London County Council.[1] Two previous reports on the encephalitis unit were made by Dr. Borthwick, the medical superintendent of the Northern Hospital, in 1926 and 1927, and he reviews here the work of the last three years. The Winchmore Hill unit now consists of five blocks, each containing twenty-five beds, and with a share of the hospital grounds as its own recreation space; two of these are reserved for boys under 16 (the applications for boys exceed those for girls), one for girls of the same class; and, since May, 1929, two blocks have been reserved for adults, male and female. With a progressive decline in the number of male applicants under 16, it is considered that one of the boys' wards will in time automatically become a male adult ward.

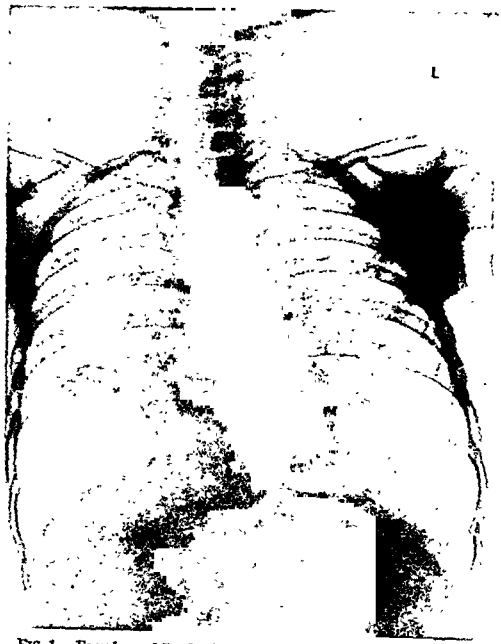

Fig. 1.—Female aged 7. Father died pulmonary tuberculosis, sputum positive. Pirquet test positive. Large Ghon's tubercle right base. Hilar disease both sides.

Fig. 2.—Female aged 3½. No known family history of tuberculosis. *Film shows* flocculent mottling in both lungs, confluent in right cardio-phrenic area. *Thickening* of right lower interlobar septum. Miliary distribution.

Fig. 3.—Female aged 4. Mother *suffering* from pulmonary tuberculosis with positive sputum. Opacity over base of right lung extending upwards along mediastinal margin. Miliary mottling throughout large part of both lungs, conglomerate in right mid area.

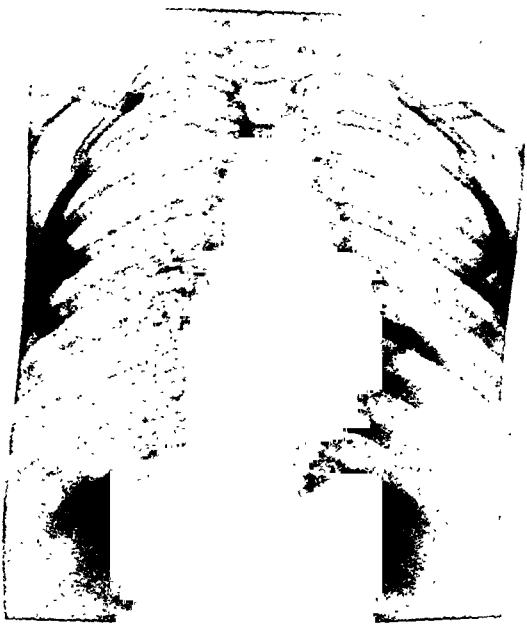

Fig. 4.—Female aged 5. Father suffering from pulmonary tuberculosis, sputum positive. Irregular glandular mass at right *hilum*. Infiltration of both perihilar zones.

FIG. 1.—Section of lung midway between hilum and pleura showing medial hypertrophy of pulmonary artery without intimal change. Haemorrhage adjacent.

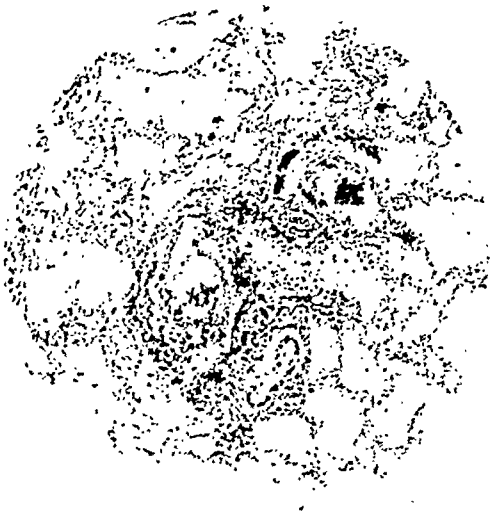

FIG. 2.—Section of lung adjacent to portion illustrated in Fig. 1, showing bronchiole and accompanying vessels. Peribronchiolar lymphocytic and polymorphonuclear infiltration. Vessels show no hypertrophic change in intima or media.

FIG. 3.—Vessel midway between hilum and pleura showing medial hypertrophy and subintimal fibrous hyperplasia.

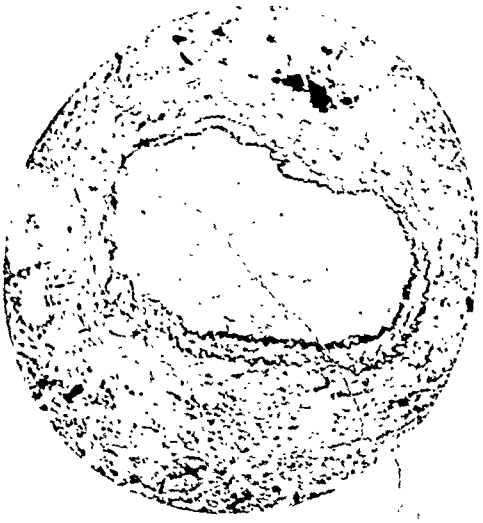

FIG. 4.—Vessel similar to that in Fig. 3 stained to show hypertrophic elastic tissue.

H. A. HARRIS: LINES OF ARRESTED GROWTH IN THE LONG BONES OF DIABETIC CHILDREN

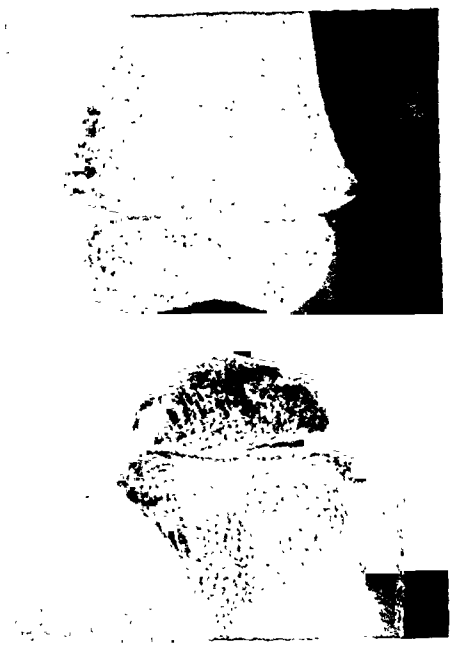

Fig. 1.—Radiogram of the knee of a diabetic girl of 13, showing multiple lines of arrested growth in the metaphysis of the femur and tibia.

Fig. 2.—Radiogram of the tibia of a diabetic girl of 12, showing lines of arrested growth in the bone.

R. S. JOHNSON AND R. R. ARMSTRONG: PNEUMONIA TREATED BY CONCENTRATED ANTIPNEUMOCOCCAL SERUM

Fig. 1.—Radiogram of chest showing pneumonia of left base and also an inflammatory lesion of the right mid and lower zones.

Fig. 2.—Specimen of left lung, collapsed and empty on the fifth day of disease. The fibrin envelope has been partly stripped to show the wrinkled surface of the lung.

H. V. MORLOCK: THE DIAGNOSIS OF EARLY PHTHISIS

FIG. 1.—Female aged 25; the only symptom was cough of seven weeks' duration. Sputum T.B. positive. The skiagram shows a typical initial infiltration in the right mid field.

FIG. 2.—Female aged 23. Skiagram taken two months after onset of cough following a short febrile attack; shows a typical initial infiltration in the right infraclavicular region.

E. J. BLACKABY: MULTIPLE OSTEOCHONDROMATA WITH OBSTRUCTED LABOUR

FIG. 1.—Radiogram of the pelvis showing growths of bone on its outer surface and a tumour of the superior ramus on either side of the symphysis.

FIG. 2.—Right knee. Multiple bony masses on the lower end of femur and on the upper ends of the tibia and fibula.

The unit is under the immediate charge of an assistant medical officer, Dr. T. R. Hill, and a consulting neurologist, Dr. Worster-Drought, visits weekly. Nursing and supervision is carried out by nurses and ward orderlies, and two fully qualified masseuses attend daily to give treatment by physical training, massage, and remedial electricity. All the children, except one or two hopeless patients, have routine lessons five days a week, and for this purpose three teachers are employed; the adults also have appropriate instructors in various crafts, and all who can are encouraged to take part in games and contests which foster the team spirit. The medicinal treatment has, rightly enough in a unit of this sort, been the subject of considerable adventure, and, though no specific remedy for the disease has been discovered, the lot of those suffering from certain phases of the disease, as well as the labours of those in nursing charge, have been considerably lightened by the use of various drugs. Thus, bulbocapnine in doses of 0.1 to 0.2 gram thrice daily by mouth or hypodermically, and liquid extract of lobelia in doses of 2 to 5 minims, were found to have beneficial effect in cases of behaviour disorders; the former drug, however, proved unpopular with some patients, owing to the depression it produces. A few cases of this class were also improved by Crofton's influenza antigen. Incidentally, it was observed that patients with conduct changes who subsequently developed Parkinsonism ceased to become troublesome in the old way; as far as the end-result is concerned, however, the onset of Parkinsonism is generally a change for the worse. For this phase (Parkinsonism) various drugs of the belladonna class have been tried, but none has proved so useful and so practicable as stramonium given in the form of pills compounded of the dried extract of the *United States Pharmacopoeia*. Cases are cited where, so long as the drug was taken regularly, the improvement in both the physical and the mental condition was very marked. Stramonium in this form appears to be well tolerated, but the mydriatic consequences of this drug and others of a kindred nature proved troublesome by depriving the patient of the power of reading. Intravenous injections of sodium salicylate were used successfully in a few cases of secondary exacerbations of the disease. The great majority of the patients, it would appear, derived more or less benefit from the ordered life of the unit, with its discipline, physiotherapy, and facilities for education and entertainment. The improvement was most marked in the milder cases of behaviour disorder, in patients with nocturnal insomnia, and in certain cases of respiratory disorders. During the five years November 13th, 1925, to November 12th, 1930, 328 cases were admitted to the unit, and of this number 49 were re-admissions, largely in respect of children who relapsed after being reclaimed by their parents against the advice of the medical authorities.

The two groups of patients at the Epsom institutions are also under the charge of a specially appointed medical officer, and at West Park section associated 84 encephalitic patients. This form is of course not a new [illegible] extended bacteriological investigation into mental patients. Many of the mental defectives in the Manor are intractable cases which have been transferred from Winchmore Hill. These three institutions, now belonging to one administrative authority, are therefore well co-ordinated, and have undoubtedly played a very desirable part in the study and expert care of post-encephalitis patients received mainly from the metropolitan area. From the social point of view it is all to the good that a considerable proportion of London's chronic cases of encephalitis have at least found safe asylum in one or other of these institutions to their own relief and that of their harassed families; and while no cure for the disease has been found, the experience gained in these hospitals, where continuous observation is possible, has proved the value of certain medicinal palliatives and other lines of treatment suitable for such types of post-encephalitis as are in any way amenable to treatment.

THE HOSPITAL ALMONER

The office of hospital almoner is growing in importance with developments in social legislation. It entails much more than the duty of assessing the means of patients who receive hospital treatment, and collecting their contributions. The hospital almoner is now a member of a highly trained profession. She is expected to be familiar with economics and social sciences and to possess certain special gifts and sympathies. She represents the social service activities of the hospital, and not only acts as a check on the abuse of hospital charity by those who can afford to pay or who are provided for in other ways, but also prevents, as far as possible, the value of hospital treatment and nursing from being frustrated by an unfavourable home environment. It is part of her task to ascertain, for the use of the hospital staff, the patients' home conditions, to co-operate with other agencies in the provision of any requisite ordered, to assist the patients to carry out the prescribed treatment, and to organize after-care on discharge. Not the least of the demands upon her resources is to have an instant knowledge of what organization—State, municipal, or voluntary—might be invoked to meet the needs of a particular case.

The social service activities of hospitals may be said to have started in 1895, first of all at the Royal Free Hospital, with the recognition that hospital treatment was often rendered largely futile if a patient's condition was due to, or aggravated by, the evils of an environment to which he was compelled to return. During the last thirty-five years, by the development of social service departments, with the almoner in charge, hospitals have greatly increased their value to the individual patient, and, through [illegible] co-operation with [illegible] to occasion better [illegible] of the Geneva Conference of 1924-25, that in order to deal effectively with the traffic in dangerous drugs regard must be had to their production *from the source*, no less than to the alkaloids and preparations derived from them, has been justified by experience, and should not be ignored.

founded in 1901, and incorporated in 1922, to select and train suitable candidates for these positions, to keep a register of trained almoners, and generally to extend and develop this side of hospital activity. Last year twenty-three certificates were granted to students who had completed their training, and thirty-nine appointments of certificated almoners to hospital posts were made. Altogether, over 130 head and assistant almoners now serving have been trained under the Institute's auspices. The report of the Institute for 1930 gives an account of the training necessary for the certificate. Students who hold a university degree in history, economics, or psychology are accepted for the practical training, which consists of a period of four months with the Charity Organization Society, and of eleven months with a certificated almoner at a hospital. Students without academic qualifications must qualify for the social study diploma or certificate of a university school of social study, which necessitates two academic sessions of nine months each, and must also, of course, take the practical training of four months and eleven months respectively. The university fees vary from 30 to 50 guineas for the two-year course, and the fee paid to the Institute for the practical training is 20 guineas. No certificate is granted to a candidate under the age of 22. Selection and advisory committees, including representatives of the university, the hospitals, and other social organizations, have been appointed in Leeds, Liverpool, Birmingham, and Newcastle, and students may take the whole of their academic work and part of their practical training in those cities, the other part being taken in London. It is hoped that, as facilities for training increase locally, a greater part of it may be undertaken outside the metropolis.

Already there is a tendency towards specialization, and five certificated almoners have taken training in mental welfare, and are now doing psychiatric social work in clinics and hospitals. The training of hospital almoners offers a very sound foundation for work of this kind, and in future, with the increasing number of such posts, and with greater facilities for training, more almoners are expected to be available. The Institute, the presidency of which has lately been accepted by Lord Moynihan, in succession to Lady Bradford, now occupies premises in a wing of the British Medical Association House, Tavistock Square.

RATIONALIZATION AND PSYCHOLOGY

Applied psychology has found a most useful field in industry, as was to be expected with the development of the idea of rationalization since the passing of the Factory and Workshop Act, 1901. This is brought out in three recent publications: *Industrial Welfare and Personnel Management*,[1] issued by the Industrial Welfare Society; the National Institute of Industrial Psychology's annual report for 1930[2]; and *How to Organize Accident Prevention*,[3] by Eric Farmer. The first pamphlet, embodying the opinions of forty-seven well-known firms, exemplifies the benefits conferred on employer and employee by the application of the principles of industrial welfare. These are, in the main, common responsibility of the employer and employed in the work of the firm, development of social activities in the direction of health, education and recreation, works committees, etc. With rationalization schemes at work the best employers have found that the promotion in the worker of a feeling of security of tenure in his position is of paramount importance. Funds are therefore raised, in some cases by deduction from all wages and salaries, for the relief of those who happen to be temporarily unemployed. There are, however, 140,000 factories in the United Kingdom and some 130,000 workshops, in the bulk of which nothing whatever is done, least of all in the direction of security of tenure. Mr. Seebohm Rowntree has established four new industries in the neighbourhood of his firm's works to absorb surplus labour. How necessary this is appears from his statement that the percentage of misfits has been reduced from 25 per cent. to 5 per cent. through the use of vocational selection. The National Institute of Industrial Psychology came into existence in 1921, partly in order to apply the principles set forth by the Industrial Fatigue (now Industrial Health) Research Board. In the annual report for 1930 instances are given of the excellent work of the institute, such as a saving of £5,000 a year in a potted meat factory, and increased output of 60 per cent. in a rubber goods factory. Although the word rationalization is rarely, if ever, used, the successes obtained are obviously due to the study of details by the institute's able investigators, leading to new lay-out, improved routine, reduction of unproductive time, standardization of methods of work, and the selection of personnel. In one department "four girls maintain the output for which eleven had previously been required." Nothing is said about what happened to the surplus seven. The institute regards the subject of vocational guidance as an important part of its work, and brief particulars are given of what has been done in Birmingham and elsewhere in testing children from schools, and in Borstal institutions. Reading between the lines, however, it is evident that much has yet to be learned, although the institute seems to set no bounds to the extent to which this aspect of its work can be carried. Thus, in his paragraph on tests for perseveration, Dr. Pinard has "prepared a list of eighty-four rateable characteristics which have been associated by various psychologists with perseveration. The subjects to whom he gave his tests of perseveration were assessed on these characteristics, and the results are opposed to Jung's theory that perseveration affords a basis for the division of people into two types—introvert and extrovert. Dr. Pinard found that his tests supplied a basis for division into three types. The moderate perseverators and the moderate non-perseverators form a stable, reliable group which, in particular, have most of the qualities needed in 'leadership.' Both extreme perseverators and 'difficult' non-perseverators prove to be unstable while the former are rebellious,

'nervous,' sensitive, and effeminate, the latter are irritable, suspicious, critical, and inconsiderate." With its limited funds the institute is obviously doing important work. A high compliment was paid to its value in the "National Plan" recently published in the *Week-End Review*, where it was said: "The utter failure to apply in industrial production as a whole the knowledge gained in psychology is a primary reason for the friction, inefficiency, and low output which are crippling British economic strength."

BACTERIAL COMPLICATIONS OF FILARIASIS

In 1926 the Royal Society, with the co-operation of the London School of Hygiene and Tropical Medicine, originated an investigation into the bacterial complications of filariasis in British Guiana, and into the so-called "endemic nephritis" of that region. Dr. A. W. Grace, the bacteriologist at Jamaica, was placed in charge of these investigations, and his report has now been issued as No. 3 of the Memoir Series of the London School of Hygiene and Tropical Medicine (published at 8s. in paper cover, 10s. 6d. in cloth, at the school). Dr. Grace is of the opinion that what is generally termed a "filarial attack" is really a lymphangitis, the exciting cause of which, in almost all cases, is the β-haemolytic streptococcus; and that the lymphangitis of elephantoid differs only quantitatively from that of non-elephantoid structures. The available evidence suggests that lymphangitis and elephantiasis, however, do not occur in a race, age group, or country to any extent in the absence of *Filaria bancrofti*. Moreover, subcutaneous and intramuscular abscesses unassociated with lymphangitis are generally due to staphylococci, and there is no evidence to connect them with the filaria. There is no relation between the presence of microfilaria in the blood and the nature of the skin reaction to streptococcal toxin. An examination of 68 various strains of β-haemolytic streptococci collected in British Guiana showed that 60 belonged to the *pyogenes* group, while 8 belonged to the *subacidus* group—these 8 belonging to the same serological type by agglutinin absorption. They do not bear any serological resemblance to streptococcal *subacidus* strains from scarlet fever or erysipelas cases in England or the United States. The commission's investigation into the endemic "nephritis" showed that many of the cases diagnosed as nephritis were really cases of cardiac failure, the error being due to the oedema and slight albuminuria which these patients had on admission. The disease was found to occur almost entirely in East Indians whose diet was mainly parboiled rice. It is associated with oedema of the lower limbs and ascites, sometimes with gastro-intestinal disturbances, fever, and tenderness of the leg muscles. The blood pressure is low, and there is a diminution in the blood content of cholesterol, calcium, and serum proteins, with disturbance in the albumin-globulin ratio. While it is evident that the disease is neither a nephritis nor a nephrosis, the investigation was not extensive enough to state definitely its nature; it seems highly probable, however, that it is either beri-beri or some condition like it. The report is extremely interesting. The view that clinical filariasis is really a streptococcal infection associated with the presence of the worm is of course not a new one, but the extended bacteriological investigation into the streptococci may prove of very considerable importance in the treatment of the disease. Hitherto, search has been made for an active antifilarial remedy for the treatment of filariasis; Dr. Grace's work suggests that more effective results may be expected from antistreptococcal serum. Before this can be effectively introduced in filarial countries an extended series of investigations will be necessary. Particularly it is suggested that strains of streptococci should be collected and classified in countries where lymphangitis and elephantiasis are endemic; and that a fresh filarial, streptococcal, and lymphangitis census should be made in countries where there is considerable filarial infection with little lymphangitis and elephantiasis.

THE TRAFFIC IN DANGEROUS DRUGS

The report recently presented to the Council of the League of Nations by the Central Opium Board continues to deplore the lack of information vouchsafed from some of the most important opium-producing countries, and from such States as Peru and Bolivia, whence coca leaves are largely derived. The tables furnished to the Board show no sort of agreement between the imports and exports of raw opium, while some twelve tons of morphine, at least, were known to have been manufactured in excess of what was apparently required for legitimate purposes throughout the world. Grave discrepancies have been revealed in regard to the average consumption of cocaine and heroin among populations which would appear to have been comparable in such respect. The Board is accordingly led to conclude that the information supplied to it under the terms of the Geneva Convention is insufficient to enable it to act with promptitude in dealing with the enormous amount of illicit traffic which is going on. The largest seizure of opium for some time past has just been made at Alexandria, where ten tons were confiscated on a steamer from Turkey. Only the other day more than a ton of pure opium shipped from Mediterranean ports was seized by the Federal agents in New York. It is not very reassuring to learn, in view of the need to deal with the raw materials from which dangerous drugs are derived, that the question of the production and distribution of raw opium is held to be outside the scope of the International Conference on the Limitation of Dangerous Drugs, which is to assemble at Geneva next month. Presumably, also, the export from India of opium for smoking, which annually amounts to about one million pounds in weight and yields a revenue of nearly £2,000,000, will also be excluded from consideration. It is good to know that the acreage under the poppy in India has now been reduced to 42,186, or less than a third of what it was a few years ago. On the other hand, the fact that in British Crown Colonies like the Straits Settlements, the Malay States, and North Borneo some 15 to 25 per cent. of the total revenue is derived from opium is apt, as at previous international conferences, to occasion hostile criticism. The contention of the American delegation, at the Geneva Conference of 1924-25, that in order to deal effectively with the traffic in dangerous drugs regard must be had to their production *from the source*, no less than to the alkaloids and preparations derived from them, has been justified by experience, and should not be ignored.

JOHN ABERNETHY

John Abernethy was born in the City of London on April 3rd, 1764 ; he died at Enfield on April 20th, 1831, and was buried on April 28th. "The greatest result of his life," wrote Sir Norman Moore, "has been the impetus which he gave to medical teaching at St. Bartholomew's and throughout England." The centenary of his death was commemorated on Monday last by the Abernethian Society of St. Bartholomew's Hospital, at whose invitation Sir Arthur Keith gave a most interesting address entitled, "Fresh light on John Abernethy." This was based in large part on the diaries of William Clift, one of Sir Arthur's predecessors in the office of Conservator of the Museum of the Royal College of Surgeons. The thirty-one volumes of Clift's diaries, beginning in 1811 and ending in 1842, are preserved in the Library of the College. "It was while rummaging in Clift's diaries, and being made to see Abernethy through Clift's eyes, that the great surgeon of St. Bartholomew's—the founder of your Society and School—became also a hero of mine." Sir Arthur Keith recalled how Abernethy used his influence to have Clift elected a Fellow of the Royal Society, and how the two men became fast friends.

"Then, in 1824, comes one of the most dramatic episodes in medical history—one in which Abernethy and Clift had each to play a part. Abernethy was then Chairman of the Board of Curators—the name given at that time to the Museum Committee. Clift had learned from the great and omnipotent Sir Everard Home—almost by accident—that the Hunterian documents and manuscripts had been deliberately burned.[1] The little Conservator turned in wrath from his patron, Sir Everard Home, and sought his chairman, John Abernethy, who by this time had refused a baronetcy. Of the men who had sat at the feet of Hunter, Abernethy best understood the greatness of the master, and struggled more successfully than any of his contemporaries to keep alive the example and teaching of one of the greatest medical philosophers the world has ever known. Hunter was the common hero of Abernethy and Clift. They put their heads together ; they brought Everard Home to book."

In phrases such as these the lecturer set before his hearers the personality and the career of Abernethy, and we are glad to know that his address will be published in full in the *St. Bartholomew's Hospital Journal*. At page 719 of our present issue appears a character sketch of Abernethy, signed with initials which need no interpretation to students of medical history or to students of St. Bartholomew's.

CULTIVATION OF PYRETHRUM IN ENGLAND

The issue of *Nature* for April 11th contains an interesting article by J. C. F. Fryer and C. T. Gimingham of the Plant Pathological Laboratory, Ministry of Agriculture, on the cultivation of pyrethrum in England. It has long been known that the flowers of certain species of pyrethrum (*Chrysanthemum*) possess insecticidal properties harmless to man and warm-blooded animals, but it is only within the last ten years that a detailed knowledge of these plants has become available. At present about 70 per cent. of the world's supply of pyrethrum is provided by Japan, although the plant is grown commercially for home consumption in Switzerland, France, and North Africa. Experiments in cultivation were started in England in 1925 by the Plant Pathological Laboratory of the Ministry of Agriculture, small plots being laid down on different types of soil at some sixteen centres. These experiments, which were carried out in co-operation with the insecticides and fungicides department of Rothamsted Experimental Station, demonstrated that pyrethrum could be grown and harvested successfully under English conditions, and that the insecticidal efficiency of the product was not less than that of imported samples. During the last two years evidence has accumulated that many samples of pyrethrum grown in England contain an exceptionally high percentage of pyrethrins, and the possibility of evolving improved strains is under consideration. Whether the cultivation of pyrethrum in this country is economically feasible has still, however, to be determined, and another series of experiments on a larger scale has been undertaken to ascertain the necessary data. The authors suggest that the labour costs entailed in having the flowers cut by hand would be considerably reduced if a mechanical means of harvesting could be devised. In recent years preparations of pyrethrum for use as horticultural spray fluids have been placed on the market in America, and kerosene extracts of the flowers have been widely sold as fly sprays. Although the resistance to the effects of pyrethrum has been found to vary somewhat in different kinds of insects, there seems to be no doubt that the pyrethrins, which appear to act as nerve poisons, are among the most potent insecticides known. It is not improbable that further investigation will reveal how the remarkable properties of this plant may be applied in other directions.

[1] For an account of this disaster see Sir Arthur Keith's Vicary Lecture on Clift, *British Medical Journal*, 1923, ii, 1130.

We have to announce with much regret the death, on April 19th, of Dr. James Lorrain Smith, F.R.S., professor of pathology and dean of the Faculty of Medicine in the University of Edinburgh. An obituary notice will appear in our next issue.

Sir Thomas Lewis, M.D., F.R.S., will deliver the St. Cyres Lecture for 1931 at the National Hospital for Diseases of the Heart, Westmoreland Street, W.1, on Thursday, May 14th, at 5 p.m. His subject is "Ischæmia of muscle as a cause of anginal pain."

The seventh annual Conference on Social Work will be held at Bedford College, Regent's Park, during this week-end (April 25th to 27th). The main theme of the discussion will concern the development in social work since the beginning of the present century. The principal meeting, on Saturday afternoon, will be addressed by Mr. A. M. Carr-Saunders, Charles Booth professor of social science in the University of Liverpool, when Sir Harold Morris, K.C., president of the Industrial Court, will be in the chair. Dr. Cyril Burt, psychologist to the Education Department of the London County Council, will address a meeting on Sunday afternoon on the new methods of treating the "difficult child." The conference this year is organized by the Association of Hospital Almoners.

Nova et Vetera

JOHN ABERNETHY, 1764–1831

The centenary of the death of John Abernethy on April 20th recalls that for the first quarter of last century the surgical practice in London was almost equally shared by two men who differed from each other as much physically as they did mentally. Astley Cooper, tall, handsome, genial, speaking with a broad Norfolk accent, a great operating surgeon, was the idol of students at the United Borough Hospitals; John Abernethy, "podgy," of somewhat ordinary appearance, whimsical, caustic, and no lover of operative surgery, was rather respected than loved by his pupils at St. Bartholomew's Hospital. Both alike were perfectly honest, and both were ethically correct at a time when charlatanism was rampant and professional jealousy ran so high that duels were not infrequent. Both were great teachers—Cooper the more practical, Abernethy the more philosophical. Both derived from John Hunter, and the very fact that they were so opposite serves to show the greatness of the master teacher, for no other single mind could combine all his qualities.

JOHN ABERNETHY, F.R.S.
Engraved in 1827 by William Bromley, A.R.A., from the portrait by Sir Thomas Lawrence, P.R.A., now in St. Bartholomew's Hospital.

The success of Abernethy must be attributed in great measure to his personality. With an early bias towards the Bar, he seems to have drifted into surgery almost by accident, and in 1779 was apprenticed to Sir Charles Blicke, an assistant surgeon to St Bartholomew's Hospital. Elected assistant surgeon himself at the age of 23, he had to wait twenty-eight years before he came on to the full staff as surgeon. During all those years he had few opportunities to operate, for as assistant surgeon he only had charge of beds when his senior was away on holiday, and there were no special hospitals to which he could attach himself. Astley Cooper was more fortunately placed, for, by nepotism in its best sense, he came on to the full staff at Guy's Hospital at the age of 32, and quickly developed into a great operating surgeon.

Abernethy, like all his contemporaries, based his work on human anatomy, but, unlike many, he used anatomy as a guide to physiology, as it was then understood, and was among the first of those who may be called surgeons with the mind of a physician. He taught in later years that many surgical problems might be solved by looking for constitutional defects or weaknesses; in other words, that the body worked as a whole, and that the old fable of "The Belly and its Members" was literally true. He ran his hobby too hard, but it had a kernel of truth, and was useful to the overfed and sedentary Londoners who formed the greater number of his patients.

By sheer good fortune, and early in his career, Abernethy was brought in contact with Dr. David Pitcairn, who recognized that there was a general desire in the profession for better and more scientific medical teaching. Dr. William Hunter had gathered round him in Windmill Street a brilliant collection of teachers—John Hunter, William Hewson, William Cumberland Cruikshank, John Sheldon, and Matthew Baillie—who taught both by example and by precept, and were laying the foundations of scientific surgery in a manner which had never previously been attempted in any country. The success of Percivall Pott as a lecturer probably suggested to Pitcairn and Abernethy that it might be advantageous to the hospital if regular courses of lectures were given by members of the staff. Pitcairn taught medicine, and was the first to make known that valvular disease of the heart was a frequent sequel of rheumatism; Abernethy undertook to teach anatomy, physiology, and surgery, and presently Thomas Wheeler proved himself an able apothecary and a first-rate teacher of field botany. The governors of the hospital entered heartily into the scheme, built a lecture theatre and a dissecting room in 1791, and regularized the old-standing custom of clinical teaching in the wards for all who chose to pay the required fee. The school was an immediate success, and its reputation was enhanced by a succession of brilliant physicians, surgeons, and teachers, amongst whom were Drs. John and Peter Mere Latham, Dr. Samuel Gee, Sir Lauder Brunton, Sir William Lawrence, Sir James Paget, Sir Richard Owen, and Sir William Odling.

The successful launching of the new school was due chiefly to Abernethy's lectures, which were so dramatic that he soon drew crowds to listen. Pettigrew says that his method of entering the lecture theatre was often irresistibly droll—his hands buried deep in his breeches pockets, his body bent slouchingly forward, blowing or whistling, his eyes twinkling beneath their arches, and his lower jaw thrown considerably beneath the upper. Then he would cast himself into a chair, swing one leg over an arm of it, and commence his lecture in a most

outré manner. Many of the lectures dealt with the constitutional origin and treatment of local diseases, a subject of which he never tired, and (says Dr. Peter Mere Latham, one of his pupils) he taught it with all his enthusiasm. "He so reasoned it, so acted it, so dramatized it, and then in his own droll way he so disparaged the more laborious researchers after truth, calling them 'the doctors,' and so disported himself with ridicule of every system but his own, that we accepted the doctrine in all its fullness. We should have been ashamed to do otherwise. We accepted it with acclamation, and voted ourselves by acclamation the profoundest of medical philosophers at the easy rate of one half-hour's instruction. The great Lord Chatham, it is said, had such a power of inspiring self-complacency into the minds of other people that no man was ever a quarter of an hour in his company without believing that Lord Chatham was the first man in the world and himself the second, and so it was with us poor pupils and Mr. Abernethy. We never left his lecture room without thinking him the prince of physiologists and ourselves only just one degree below him." This facility in lecturing appears only to have developed slowly, for Abernethy was essentially a shy man, and in the early part of his career as a lecturer he often had to leave the theatre to collect his thoughts.

Many of the stories of his brusqueness were undoubtedly due to this shyness, but towards the end of his life he became more whimsical and was less tolerant of patients whose illnesses were due, in his opinion, to their own loss of self-control. He was, too, a good economizer of time, so that he was always punctual, and had little patience with those who were prolix or overlong in describing their symptoms. Realizing that "time is money," he never kept his hospital patients waiting, and would refuse a consultation or cut short a garrulous person that he might be in his out-patient room as the clock struck the hour. He was no respecter of persons, and on occasion could be downright rude, as when he was consulted by H.R.H. Frederick, Duke of York. Abernethy stood before his august patient whistling, and with hands in his pockets. The Duke, in astonishment, said, "I suppose you know who I am?" "Suppose I do," said Abernethy, "what of that? Cut off the supplies, as the Duke of Wellington did in his campaigns, and the enemy will leave the citadel." In like manner Lord Tennyson used to tell of a Lincolnshire farmer who came complaining of discomfort—weight and pain—in his head. The doctor said, "How much ale do you take?" "Oh, I taakes my yale pretty well." Abernethy (with great patience and gentleness): "Now then, to begin the day, breakfast; what time?" "Oh, at haafe past seven." "Ale then, how much?" "I taakes my quart." "Luncheon?" "At eleven o'clock I gets another snack." "Ale then?" "Oh, yees, my pint and a haafe." "Dinner?" "At haafe past one." "Any ale then?" "Yees, yees, another quart then." "Tea?" "My tea is at haafe past five." "Ale then?" "Noa, noa." "Supper?" "Noine o'clock." "Ale then?" "Yees, yees; I taakes my fill then, I goes to sleep arterwards." Like a lion aroused, Abernethy was up, opened the street door, shoved the farmer out, and shouted after him, "Go home, sir, and let me never see your face again. Go home, drink your ale, and be damned." The farmer rushed out aghast, Abernethy pursuing him down the whole length of Bedford Row with shouts of "Go home, sir, go home and be damned." Yet if Abernethy was merciless to patients of this class, he was unsparing in his attentions to those who were deserving of his pity, and he died a comparatively poor man.

D'A. P.

LONDON VOLUNTARY HOSPITALS COMMITTEE

We have received from the honorary secretary of the London Voluntary Hospitals Committee a copy of the report (printed substantially in full below), containing an account of several matters of interest to hospitals which have recently been under discussion between that committee and the Central Public Health Committee of the London County Council.

CONFERENCES WITH THE CENTRAL PUBLIC HEALTH COMMITTEE

The London Voluntary Hospitals Committee has now been in existence for a year. It was specially set up for the purpose of consultations with the London County Council under Section 13 of the Local Government Act, 1929, the elections taking place in accordance with a scheme drawn up by a Joint Committee of King Edward's Hospital Fund, the Conference of Teaching Hospitals, and the London Regional Committee of the British Hospitals Association. A broad interpretation has been placed upon Section 13, both by the committee and by the Central Public Health Committee of the London County Council. To quote a recently published report of the latter body to the Council:

> "The voluntary hospitals representatives, for their part, have disclaimed any wish to press for a strict reading of the section where small matters are concerned, and we on our part have readily acceded to their wish to be consulted at an early stage on all matters of moment. Mutual desire was expressed, and agreement come to, that the machinery of Section 13 of the Act of 1929 should be used for exchange of information to the advantage of both the public and the voluntary hospitals services."

The meetings which have taken place between representatives of the two bodies are referred to by the Central Public Health Committee as "interesting and helpful." The committee has been assured by the chairman of the Central Public Health Committee that the committee receives the earliest information it is possible to give concerning the schemes projected by the Council.

The committee has kept in touch with its constituent hospitals by means of a series of reports, which have also been sent to the members of the area committees and Non-localized Special Hospitals Committee, by whom the central committee is elected. No occasion has yet arisen to call together the area or other committees for consultations, as the London County Council decided at an early date to postpone the area organization of their own services that had been foreshadowed.

Grants to Voluntary Hospitals

Among matters which have been discussed by the committee with the London County Council are questions relating to the financial policy of the Council in regard to voluntary hospitals. The committee has ascertained that there is no present likelihood of the Council departing from their existing practice of not making capital grants to voluntary hospitals. As regards maintenance, while the Council are not disposed to make grants for general maintenance, they are willing that payments for specific services required by the Council and rendered by voluntary hospitals to the sick poor should be continued, and that the application of this principle should be, if possible, extended. It will be remembered that this distinction was also drawn by Lord Cave's Committee. The Council have agreed to the committee's request that as an interim arrangement contributions to voluntary hospitals of similar amounts to those contributed by the late guardians in 1929 should be paid for the year to March 31st, 1931, by the Council, on the understanding that the payments are without prejudice to whatever financial arrangements the Council may decide to make after that date.

The committee's representatives at their last conference with the Central Public Health Committee strongly urged that the Council should not rigidly insist upon themselves treating all patients chargeable to them, if there were a choice of voluntary or Council accommodation. The Council took the view that it is their first duty to keep their own beds occupied, and that, while they cannot pay voluntary hospitals for services they can themselves supply, they adhere to the principle as to grants for specific services rendered at their request.

The Council have submitted to the committee for its observations their proposals for scales of salary and conditions of service for medical staff, nurses, stewards, and clerical staff.

Pathological Service for Council Hospitals

The provision of pathological laboratories at the Council's hospitals has been discussed with the committee. The Council have in mind as an ultimate ideal a well-equipped and adequately staffed laboratory in every general hospital, and one or more central laboratories for the specialized pathological work requiring expert knowledge and elaborate equipment. Their immediate proposals provide for the establishment of five "group" laboratories, suitably located, capable of dealing with the more specialized pathological work. The first of these "group" laboratories will be ready to function this month. Two others will be completed in three or four months' time. The last two will be ready for use towards the end of this year. The late Metropolitan Asylums Board had already provided adequate laboratory services at the northern and southern "group" laboratories for the special hospitals, and also for the production of therapeutic serums at Belmont Laboratories. The committee cordially agreed with the view that it was most desirable to provide an adequate pathological service for every general hospital dealing with acute cases, and recommended that in the formation of "group" laboratories advantage should be taken of existing pathological departments of the voluntary hospitals, though the Council did not eventually see their way to adopt this suggestion.

The committee was, at an early stage, given an opportunity to consider the rates of pay proposed by the Council for pathologists and technicians, and was able to arrive at an understanding concerning the very few cases in which its views differed from those of the Council. The Council have recently published details of their decisions in this matter.

Medical Education in Council Hospitals

A memorandum was prepared by the committee, at the invitation of the Council, upon the use of municipal hospitals for medical education, and upon the methods of staffing that the committee would recommend. It was submitted that the appointment at the municipal hospitals of resident house-physicians and house-surgeons would prove of the greatest value in the post-graduate education of recently qualified men and women. The Council concurred in this suggestion, and provision has already been made for such appointments. The committee also recommended that the present consultant services at municipal hospitals be extended, and that an advisory board or boards be constituted by the Council for the purpose of recommending consultants for appointment by them. The Council, however, decided that the existing arrangements shall be continued and reconsidered in a year's time, when further experience has been obtained. Opportunities for students to visit municipal hospitals for the purpose of studying diseases more often seen in those institutions than in voluntary hospitals have been much appreciated. Therefore the committee suggested that such opportunities should be extended by encouraging closer co-operation between teaching and municipal hospitals wherever possible. This suggestion was accepted by the Council.

Maternity Beds for Teaching Purposes

The committee discussed with the Council the shortage of obstetric beds at teaching hospitals for instructing medical students. The suggestion had been put forward by responsible committees inquiring into kindred matters that some arrangement should be made whereby cases in rate-supported hospitals might be made available for medical students. A subcommittee was appointed, and several eminent obstetricians, not themselves members of the committee, were co-opted to serve on it. The medical schools were also consulted. The recommendations of the subcommittee subsequently formed the basis of a discussion with the County Council. The Council, while stating that the existing maternity units in their general hospitals were not of sufficient size to be suitable for teaching purposes, and were fully used for the training of nurses, acquiesced in the principle of allowing the teaching of students in connexion with their maternity beds as and when satisfactory arrangements could be made and suitable units were available.

Inquiries have been made regarding responsibility for providing in-patient accommodation for maternity cases as between the County Council and the metropolitan borough councils, grants for this purpose having been made in the past by the Ministry of Health. It has been suggested by the Council that voluntary hospitals seeking maintenance grants towards additional maternity beds should make their applications to the borough councils, as being the maternity and child welfare authorities in London.

Mental Treatment

The committee arranged two conferences, which took place at the Board of Control in connexion with the Mental Treatment Act, 1930. Representatives of the Board outlined the facilities provided by the Act for treating mental patients in voluntary hospitals, and drew attention to the power of the county authorities to contribute to the cost. The Board has been requested to keep in touch with the hospitals, and to forward details of their requirements regarding the accommodation to be provided when available.

Through Lord Riddell's illness the committee has for some months been deprived of its chairman, who has, however, now returned to active affairs. Sir Henry Jackson has been elected deputy chairman, and has acted as chairman in Lord Riddell's absence. Mr. E. Vernor Miles is the honorary treasurer, and Dr. Geoffrey Evans the honorary secretary.

WEST LONDON POST-GRADUATE COLLEGE

SIR HENRY SIMSON ON POST-GRADUATE OPPORTUNITIES

The opening session of the West London Post-Graduate Medical College was held at the West London Hospital, Hammersmith, on April 15th, when Sir HENRY SIMSON, the dean, delivered an address on the importance of post-graduate study, and explained the system of education pursued at the College. He began with a reference to the impending reconstruction of West London Hospital, whereby extended accommodation will be available for patients, with provision for paying patients, for whom there will be a sliding scale of fees. He mentioned that the medical staff of the hospital had given a donation of 500 guineas towards the building fund.

Several methods were available, Sir Henry Simson continued, for the man in practice who desired to take up some form of continuing education. One of the oldest systems was for the young doctor to become assistant to, or partner of, an older practitioner; another was for him to obtain a post as house-physician or house-surgeon in a hospital. But the value of the first of these methods depended, obviously, on the experience of the senior and his ability or willingness to impart it; while as to the second, only a limited number of appointments were available. There were other ways open, of much more importance to the generality of medical men. A method which had been for many years well recognized on the Continent, particularly at Vienna, was the setting up of

a great post-graduate school. The school at Vienna had a high reputation, and attracted doctors from all parts of the world; a large hospital of over 1,000 beds was attached, with all the leading medical men of Vienna on its staff, and there were excellent laboratories and every facility for research. A great imperial post-graduate college on these lines, situated in London, and staffed by the leading men in the profession, was certainly the ideal, and he hoped that for the credit of the profession such an organization would come into existence. But the financial undertaking would be very large, and in London especially there would be difficulty in securing staff, because the undergraduate schools attached to the great hospitals absorbed the available teachers. A second method was through such a development as the Fellowship of Medicine, housed at present in the premises of the Royal Society of Medicine. The Fellowship was undoubtedly doing a very valuable work, and its secretaries were in touch with all the London hospitals, where intensive courses were arranged throughout the year. It suffered, however, from the fact that it could not supply all the facilities for instruction under one roof. The third method was the one made available by the West London Post-Graduate College, started many years ago by the late Mr. Leonard Bidwell. It offered, what the great majority of practitioners most wanted, a place where they could go and examine a large number of cases of many different kinds of disease.

Certain difficulties stood in the way of the practitioner desiring to undertake post-graduate training. The general public, to begin with, had not been educated to recognize the value of post-graduate education. A certain number of people were inclined to say that a man could not be a really good doctor because he found it necessary to go back to the hospital for instruction. In America, where the public were fully alive to the importance of post-graduate study, the contrary was the case. Several post-graduate societies were established in the States, and practically every year 200 or 300 members of those societies came over to Europe together and made a tour of the important medical centres. The idea of the American patient was that unless his doctor took advantage of one of these tours every now and then, he could not be a progressive man, alive to modern developments in medicine. A further difficulty of the general practitioner was to secure time for post-graduate study. He was uncertain of his hours, and could not always get away for a scheduled course. All sorts of emergencies might hold him up. Moreover, to take a short intensive course was expensive, not on account of fees, but owing to the arrangements he had to make for his practice to be carried on in his absence. His annual holiday seemed too precious for a fortnight of it to be earmarked for post-graduate work. Altogether the special circumstances of the general practitioner were best met by a large general hospital, easily accessible, and with large out-patient and casualty departments. Any of the under-graduate teaching hospitals in London would meet this need were it not for the impossibility of effectively combining undergraduate and post-graduate teaching. The undergraduate wanted lectures and elementary instruction in diagnosis. The graduate did not so much want lectures; discussions on prognosis and treatment were likely to be of far more value to him than the comparatively simple matter of diagnosis.

It was with this idea in mind that Bidwell conceived the plan of the West London Post-Graduate College. Only graduates were allowed to attend hospital practice there, and every day, from 10 to 5, the departments were available for continuous instruction by different members of the staff. Special facilities were given to practitioners in the neighbourhood of the hospital, who, on taking a yearly ticket for a small sum, were enabled to spend an hour or two in the hospital at any time they happened to be free. Sir Henry Simson pointed out the large area served by the hospital—the whole of London west of Hyde Park Corner—and said that the present handicap, lack of accommodation, would, he hoped, soon be remedied under the energetic lead given by the chairman of the hospital, Sir William Wells.

England and Wales

Centenary of Leeds School of Medicine

The centenary of the Leeds School of Medicine will be celebrated by the University on June 30th and July 1st. The ceremonies include a civic reception by the Lord Mayor of Leeds (Dr. Arthur Hawkyard), an honorary degree congregation, a visit to the Leeds General Infirmary, a dinner, and a ball. The celebration marks the centenary of an institution known successively as the Leeds School of Medicine (1831-84), the Medical Department of the Yorkshire College (1884-1904), and the School of Medicine of the University of Leeds (since 1904). Among the founders were T. Pridgin Teale, sen., still quoted in *surgery*; sons of the famous William Hey; and C. Turner Thackrah and Sam Smith, whose researches on the relations of industry and disease had a substantial influence on the passing of the first Factory Acts. There has not been any period in which a distinguished name has been wanting, and within living memory T. Pridgin Teale, jun., Clifford Allbutt, Wheelhouse, Jessop, McGill, Mayo Robson, and Moynihan (the last two being still members of the School) have all contributed largely to the progress of medicine and surgery. The century has witnessed a very great consolidation of academic and clinical interests and a substantial increase of accommodation and equipment for teaching and research in all branches.

Home Ambulance Service

It is apt to be forgotten that the extensive organization of an efficient ambulance service is largely a post-war development. This fact is strikingly brought out in the twelfth annual report of the Home Service Ambulance Committee of the Order of St. John and British Red Cross Society for 1930, which contains a brief historical survey of recent progress. In 1906 a Government committee was set up to inquire into the provisions that existed for dealing with accident and sudden illness in the streets of London, and reported that 60 per cent. of the street casualties outside the area of the city were transported to hospital by some mode of conveyance other than by litter or ambulance. It found that improvised vehicles such as carts and cabs had been utilized for conveying patients with fractures of the spine, skull, and pelvis, and concluded that more than a third of the seriously injured or incapacitated were transported by means likely to aggravate their condition. In the large provincial towns arrangements for invalid transport were, as a rule, equally unsatisfactory. Plymouth, for example, had no motor ambulance for civilian needs in 1914, a few hand-propelled litters being used by the police in cases of accident. In that district to-day there is a large three-storied central ambulance station and substations at Devonport and Stonehouse. In 1921 the number of cases dealt with was 3,020; in 1929–30 the number was 24,826. Before the war conditions in country districts were even worse than in the towns, since patients confined to bed had little hope of treatment outside their own homes. Strenuous efforts have been made by the Home Service Ambulance Committee to organize efficient services in rural areas, not only by providing vehicles at selected stations, but in linking up invalid transport with first aid. The meritorious work of the auxiliary branches—the first-aid road service and the mobile *x*-ray service—have been frequently referred to in these columns. According to the report a new mobile *x*-ray outfit has been designed by the committee's radiographer, which is considered to be as efficient as the stationary installations in the *x*-ray departments of the

large hospitals. In a general review of the year's work, the committee states that 325 ambulance stations have been established, including 95 ambulances affiliated to the service. During 1930, 111,335 patients were transported, bringing the total number carried since the service was instituted up to 958,400. About a dozen stations have been equipped since the last annual report was issued.

Royal Sussex County Hospital: New Operating Block

A new operating block at the Royal Sussex County Hospital, Brighton, was opened by Lord Moynihan, President of the Royal College of Surgeons, on April 16th. An extension of the operating theatres at this institution has been proposed for some time, and when in 1929 the number of operations performed at the hospital during the year reached 2,600, having been only 1,700 in 1925, the board felt that it was not in the best interests of the patients to delay further the erection of larger and more up-to-date theatres. The building of the new block was therefore started, the construction being based on an experience gained regarding the theatres of some twenty other hospitals. The Royal Sussex County Hospital had made a centenary appeal for £100,000 in 1926, but the sum realized was only £45,000, insufficient for progress to be made with regard to the theatre services. Therefore a special theatre fund was opened in 1929, and received some generous donations, amounting to close upon £9,500, leaving about £6,000 still to be collected. The total expenditure on the new operating block has been £15,500, this including the cost of constructing a necessary corridor bridge between the block and the main building. The block comprises two theatres, with a central sterilizing room, two anaesthetic rooms, a room for the surgeons, an *x*-ray room (not to be equipped until funds are available), and rooms for auxiliary purposes. In addition to furniture transferred from the existing theatre, new antiseptic equipment has been purchased, costing not far short of £1,000.

Lord Moynihan, addressing a gathering presided over by Major Lawrence Thornton, president of the hospital, and including the Mayor and Mayoress of Brighton and other prominent Sussex people, said that he liked always to give his best support to the principle of the voluntary hospitals. One heard on all hands, especially since the advent of the present Government, that the voluntary principle was moribund, out of tune with the times, and incapable of enabling hospitals to fulfil their obligations to the community. But under the voluntary system the hospitals of this country, outside London, showed an excess of £1,250,000 of income over expenditure, and added not fewer than 1,000 beds to their accommodation every year. The voluntary principle was not dead; it was still in its infancy, but it required much better organization than it had yet received. Incidentally, in describing hospitals as the training ground for doctors and nurses, Lord Moynihan paid a warm tribute to nurses, and said that as one who had had a measure of success in his profession he bore his honours guiltily, because so much of what he was supposed to have done had really been done by the nurse. He believed that no hospital in the country dealt with nurses as they deserved to be dealt with, and there ought to be much more adequate remuneration for them and better provision for their future. Incidentally, Lord Moynihan received, on behalf of the nursing staff at the Royal Sussex, a presentation of £55 10s. as a contribution of the nurses towards the theatre fund. With regard to the new operating theatre —except as regards one matter which with him was a personal whim rather than a professional criticism—he had never seen anything better in any institution he had visited. The spirit of the hospital was quite admirable, and he considered it a signal honour to be allowed to associate himself with the work that was being done.

Leicester Public Medical Service

The report of the board of management of the Leicester Public Medical Service for 1930 shows that the activities of this service are being well maintained. There were sixty-seven fewer subscribers to the various sections of the service than in 1929, mainly due to a falling off of subscribers to the people's dispensary and the Star benefit. Arrangements are being made whereby the fee for medical attendance on members residing in the county shall be higher than that paid by city members. The board points out that, as a result of industrial depression, money has been difficult to collect, and urges acting members to advise suitable people to become subscribers to the Public Medical Service. The number of prescriptions during 1930 was 216,169, as compared with 228,776 in 1929. There has been an increased attendance during the past year in the ophthalmic, aural, radiological, and dental departments. The benevolent fund, established and maintained by donations from the trustees of the late Miss Sarah Barlow and the medical profession in Leicester, has greatly assisted those uninsured patients unable to buy insulin at the ordinary price. It is proposed to revise the Leicester pharmacopoeia by adopting the national formulary. The report of the committee of the Union of Medical Practitioners (Leicester Subdivision) for 1930 confirms the excellence of the scheme for collective locum-tenencies. Donations to medical and allied charities amounted to £128 15s.

King Edward VII Sanatorium, Midhurst

In the twelve months ending July, 1930, there passed through King Edward Sanatorium 207 patients, as compared with 187 in the previous year. Since October, 1924, artificial pneumothorax has been performed on 98 patients; 72 of these have continued this treatment since leaving the sanatorium, and of these 63 are still alive, 44 having no sputum now, or no tubercle bacilli in it. Refills have ceased in 32 of these 63, and 26 of them have now no expectoration, or it is tubercle-free. All the cases were positive before pneumothorax was first induced. In the pathological department the investigation of the filterable stage of the tubercle bacillus has been continued, and no evidence has been found that such filtrates can produce a true tuberculous inflammation, nor have bacilli been detected in the lesions produced by filtrates. The statistical department publishes as hitherto an account of its study of the ultimate results in the case of patients of differing degrees of infection. Copies of the report may be obtained (price 1s., post free) from the medical superintendent, the Sanatorium, Midhurst, Sussex.

The Late Lord Stamfordham

The Management Committee of King Edward's Hospital Fund for London has adopted a resolution placing on record its sorrow at the death of Lord Stamfordham, whose connexion with the work of the Fund began in 1901, and who, from the time of the passing of the Act of Incorporation in 1907, had been a member of the council.

"As the result of the direct personal supervision exercised over the Fund by its Royal President, Lord Stamfordham, as his private secretary, was, during the years 1901 to 1910, brought into close and almost daily touch with the details of its work; and from 1910, when the King, on his accession, became its Patron and declared his unabated interest in all that concerned its welfare, Lord Stamfordham continued his association with the Fund in his double capacity as a member of the council and as the channel of official communication with His Majesty. Throughout the whole of this period of thirty years the Fund had the benefit of his vast experience and his unfailing wisdom, tact, and charm in dealing with men and affairs, and his presence and assistance will be very greatly missed."

Scotland

Paying Patients in Hospitals

The Right Hon. William Adamson, M.P., Secretary of State for Scotland, opened on April 2nd, at the Royal Victoria Infirmary, Glasgow, a new building which is intended to provide treatment for patients who occupy a position between those for whom free attendance is admissible and those whose finances permit of expensive treatment at private nursing homes. Mr. William Gray presided, and stated that this extension of the general hospital services was in the nature of an experiment. As a result of the report of the Departmental Commission appointed in 1925 to inquire into hospital services in Scotland, the governors of the Royal Victoria Infirmary had decided to provide accommodation for a section of the community for which little provision at the present time existed. They had been able to offer a moderate scale of fees, amounting to six guineas per week for the first three weeks, and three guineas per week thereafter. The patient therefore would know exactly what his financial responsibilities were before he entered the hospital. In declaring the annexe open Mr. Adamson recalled that since the first building of this hospital was opened in 1890 with eighty-four beds, many advances had been made. The accommodation in the main hospital was now 380 beds, and various facilities had been added with the progress of knowledge, including a large outdoor dispensary, a convalescent home, and an auxiliary hospital. The present experiment, he thought, would be successful. In his opinion this extension of the hospital services was bound to come. It would be self-supporting, and it would in no way interfere with funds for the treatment of patients who could not afford to pay anything, so that the charitable work of the Infirmary would be continued as before. It was ideal that a paying annexe should form an integral part of an infirmary, for this ensured to the patients all the advantages which only a large, modern, and fully equipped medical institution could provide. This experiment in a new field of public service would be watched with the closest interest, and he congratulated the governors on their enterprise. The annexe forms a wing of five stories, the ground floor being devoted to accommodation for nurses, and the first and second floors containing two wards, each with twelve beds, and, in addition, eight single rooms for special surgical cases. Each floor has a small kitchen for special cooking, and a day room for the use of patients who are able to move about. Admission to this department will be restricted to persons whose income does not exceed £500 per annum, and the treatment will be the same in all respects as that provided in the other wards of the hospital.

Edinburgh Maternity Hospital

At the annual meeting of the Edinburgh Royal Maternity and Simpson Memorial Hospital, held in the City Chambers, Edinburgh, on April 10th, Lord Provost Whitson, who presided, mentioned that the number of patients treated in the wards of the hospital in the past year—namely, 2,469—was the highest since the foundation of the hospital, being an increase of 118 over the figure for the preceding year. The total number of cases, including outdoor cases and those dealt with by the Leith branch of the hospital, was 3,506—an increase of 225. Women, he said, were availing themselves more and more of the ante-natal clinics; during the past year the total number of attendances at these clinics was 10,000, while at a post-natal clinic the attendances numbered 1,315, and at a baby clinic, 534. These figures all showed a considerable increase over those for the previous year. The revenue for the past year amounted to £12,902, and the expenditure to £14,978. To balance this deficiency the directors had been compelled to draw on the reserve fund; this was a matter for regret, because legacies could be regarded only as fortuitous gifts. With regard to the amalgamation of the hospital with the Royal Infirmary, the erection of a new and up-to-date maternity hospital on the site of the present George Watson's College at the Meadows would form part of the building scheme, but it would be at least five years before this maternity pavilion was ready. He therefore emphasized the necessity of obtaining a larger annual income from subscriptions, because the increasing work of the hospital was demanding a constantly increasing expenditure.

Kilmarnock Drainage Scheme

An inquiry was opened on April 15th by the Scottish Department of Health in Kilmarnock into a proposal of the corporation to introduce a new drainage scheme by which the burgh sewage would be carried directly to the sea in pipes instead of being passed into the open river as at present. It is proposed to carry the outlet of the sewer three hundred yards below the low water mark of the ordinary spring tides. Objections were lodged on various grounds by neighbouring burghs, the railway company, by golf clubs, and by some private individuals. It was pointed out that the disposal of the burgh sewage, which had been a problem for about thirty years, could be solved by either subjecting the sewage to some system of inland purification, or by having it carried direct to the sea. The first suggestion, however, involved certain difficulties—namely, the disposal of residual sludge, the elimination of unpleasant odours, the formation of a breeding-ground for flies, and the occupation of land which might be useful and valuable for other purposes. At present the sewage is discharged into Kilmarnock Water by nineteen main outfalls and by some hundreds of private pipes, with consequent pollution of the river. Dr. J. R. Currie, professor of public health in the University of Glasgow, described the proposed scheme as one of outstanding merit. It would enable the sewage to be discharged into the sea at a point where it would be immediately absorbed in a very large volume of water, and pollution of the beach would be infinitesimal.

Glasgow Hospital for Sick Children

At the forty-eighth annual meeting of the Glasgow Royal Hospital for Sick Children, the Earl of Home, who presided, spoke of the proposed addition of a completely equipped orthopaedic department. It was intended that this should form the centre for orthopaedic work in Glasgow and the central and south-western districts of Scotland. He referred to the Orthopaedic Hospital in course of construction near Edinburgh, which would be completed within a year, to serve a similar purpose for the south-eastern area of Scotland, and to the country branch of the hospital, opened last autumn, which would be able to treat 1,000 children every year at an annual cost of about £6,000. In seconding the report the Rt. Hon. William Adamson, M.P., said that 5,247 children had been treated in the wards of the hospital, and that out-patient attendances numbered 89,103. It was satisfactory that, despite trade depression, the year's income had enabled all this good work to be done. Moreover, the hospital had kept in close touch with the outside world by the teaching, training, and research that had been carried out in it. This was an important consideration. Referring to the proposed orthopaedic department, he said that this would fit in with the public child welfare service, with the school health service, and with the children's department of every hospital through the area, and would therefore provide a magnificent example of co-operation in a vital public service.

Correspondence

THE POST-INFLUENZAL COUGH

SIR,—I am able to confirm, from a large number of cases during the past winter, the accuracy of Dr. G. Richardson's observation in to-day's issue of the *Journal* (p. 655) that, in the majority of cases of post-influenzal cough, the cause is tracheitis. Further, I would like to suggest that tracheitis is by far the commonest cause of all varieties of chronic or semi-chronic cough in infants and children, although the cause is usually ascribed to bronchitis. In babies at least, bronchitis is a very severe condition, whereas the tracheitis which follows the common cold or influenza, though a troublesome condition, is not really a very serious matter, or one giving rise to severe constitutional symptoms. The tracheal origin of the troublesome cough which so often succeeds influenza or the common cold can easily be proved by pressing with the finger on the trachea just below the larynx. This operation immediately elicits a cough. I have found that ammonium iodide, in combination with compound tincture of benzoin, together with counter-irritation, with some stimulating liniment applied to the front of the neck, is the most useful form of treatment.—

I am, etc.,

ERIC PRITCHARD.

London, W.1, April 18th.

POISON GAS AND PULMONARY CANCER

SIR,—In to-day's issue of the *Journal* (p. 667), Dr. H. E. Collier inquires whether there have been "numerous cases of pulmonary neoplasm, following gassing, etc., on war service." It has been suggested by Kraus[1] that the increase of lung cancer since the war may possibly be due to poisoning by war gases, as the disease preponderantly affects the males. Huguenin,[2] Probst,[3] and others have discussed this question, and have stated that there is no evidence that war gas is a causative factor in the disease. Apart from these I know of no other references on this subject in the literature.

In a series of sixty-two cases of primary cancer of the lungs and bronchi which I have been studying, four of the patients were gassed in the war.

1. A man who died in 1927, aged 44, was badly gassed and wounded in the chest in 1917.

2. A man who died in 1925, aged 47, was badly gassed in 1918.

3. A man who died in 1928, aged 49, was badly gassed in 1917.

All three were left with chronic coughs, which persisted until death.

4. A man who died in 1929, aged 42, was a gas instructor during the war. He was never badly gassed, but used to go into gas-filled rooms without a mask.

I am inclined to think that the subject warrants rather more attention than has hitherto been given to it.—

I am, etc.,

WILLIAM BROCKBANK.

Manchester, April 18th.

"CANCER AND SCIENTIFIC RESEARCH"

SIR,—The book with the above title, by Barbara Holmes, Ph.D., noticed in the *Journal* of February 28th, deals with biochemical factors which have been the object of my researches for some twenty-five years; therefore I beg the courtesy of your columns for a few comments.

To the lay public the section of the book dealing with immunity appeals most directly. We are told that serums, analogous to antidiphtheritic serum, "can *now* be prepared" (italics mine), and that "the most successful serum from the point of view of its selective action, so far described, is made by injecting human breast cancer into a sheep"; also, that it "introduces a distinct element of hopefulness." I must point out that this is not a new discovery. In a paper on "Some reactions of the blood after cancer inoculation," read at the International Congress of Medicine, London, 1913, I described the method of the late G. C. Purvis (Grahamstown). He had inoculated a sheep several times with some "fungoid growths" cultured from cancer tissues with a little of the cancer material (epithelioma and scirrhus) in which these vegetable growths were developing, and with some of the culture solution (sodium salicylate and saline). He obtained definite necrosis of a large cancerous mass (epithelioma) of the face by injecting 2 or 3 c.cm. of the inoculated sheep serum subcutaneously in the arm. He attributed his result to the action of a true immune serum. In 1912 he was in London, and I examined some of his sheep serum in the physiological laboratory, King's College. The reactions I obtained corresponded with those of antidiphtheritic serum as previously published by me.

Having found (1910) that single inoculations of animals with normal and cancerous tissue, or with normal and cancerous serum, increased tissue lipolysis, I decided to try cancer tissue obtained fresh after operation, instead of Purvis's culture material. So, with Professor Hewlett, I inoculated fresh human breast cancer several times into a sheep, a goat, and a rabbit; also mouse cancer tissue into rats. In no case did the grafts grow. The serum reactions corresponded to those of Purvis's sheep serum, showing a slightly diminished lipolytic activation and lessened antitryptic power. It may be a small point, but no reference is made by the author of this book to the work of Purvis or to my own. I also inoculated a sheep several times with serum of a patient suffering from generalized cancer in the abdomen, and I used the resulting sheep serum by subcutaneous injection in small doses, with apparent benefit to the patient. Employing a patient's own serum to prepare sheep serum would seem to obviate the difficulty mentioned by the author of being sure of the particular type of cancer tissue to use, or the removal of a piece of growth first for inoculation of the sheep, often an impracticable procedure in cases of deep-seated disease. The great expense and time involved, with the total lack of support, precluded me from further investigation of this promising line of research.

In 1924 I repeated the inoculations with cancer serum in a sheep and a rabbit with confirmatory results. I found that injection of antitoxin in diphtheria increases lipolysis, which is decreased before treatment. Presumably a similar increase occurs in cancer after injection of the inoculated sheep serum. I showed at the same time that in progressive cancer the lipase-activating power of the serum is decreased, and that it returns to normal, or is increased, after successful treatment. This (then new) biochemical fact of defective serum action on lipase, though not specific, has since been amply confirmed. I found definitely (1911) that the serum of mice which had recovered spontaneously from large cancer growths had an increased lipase-activating power.

It is clear that the body can immunize itself, or attempts to do so. In this, assistance can be given; for instance, since 1905 I have advocated sodium oleate—orally, subcutaneously, or intravenously. Sodium oleate was introduced by Webb of Melbourne in 1901, and proof has been forthcoming of the value of the fatty acids in certain forms of cancer. Nakahara used sodium oleate with good effect in mouse cancer. Further, in 1919 I made saponified extracts of human breast cancer tissue, hoping that they might be more effective. The

[3] Probst, R.: *Zeit. Krebsforsch.*, Berlin, 1927, xxv, 431.

only opportunity I had of testing it—and the result was very good—was after surgical removal of a rapid recurrence of an extremely malignant type of growth. I made and suggested also saponified extracts of other pathological tissues. If parasite or virus be present, saponified extracts will contain derivatives from them; indeed, Carl C. Warden described specific fats and fatty acids of cells "bacterial and somatic" (similarly saponified) as "specific antigens" in immune processes.

As to failure to reinoculate spontaneously recovered mice, and as to rats made non-susceptible by inoculation of normal tissues, the author notes that "outgrowing of the tissue cells and blood vessels is absent," and there is no sign of any positive agent at work which might have a lethal effect on the graft. . . . It fails to elicit any sort of response." Why is no reference made to my explanation of these phenomena, that "lipoclastic acceleration [used then in the sense of an increase of lipolysis] is one factor in the natural defence or protective processes of the body and in the induced resistance or immunization to inoculated tumour in mice"? (*Journ. Phys.*, 1911, xlii, 11.)

The same query applies to Dr. Murray's statement in the eighth Scientific Report, Imperial Cancer Research Fund, 1923, of "a hitherto unsuspected result, that the induction of a fresh primary growth after a first has been definitely established meets with a very intense resistance. . . . The nature of the refractoriness is obscure. . . . Its greatest interest and importance lies in the indication it gives of a systemic constitutional change in the organism in which cancer has developed." As I showed in 1913: (1) Primary cancer inoculation is followed by an increased action of the serum on lipase, which is estimated by neutralizing the fatty acids set free. (2) In established cancer this action of the serum is decreased, and the antitryptic power increased. (3) Injections of patients' own serum in two cases of inoperable cancer (method of autoserum treatment) were followed by increase of the action of their serum respectively on lipase, as compared with the decrease found before treatment; the antitryptic power of the serum was reduced to normal or subnormal, compared with a high increase found before treatment, and was followed by lasting recovery in both cases. In addition to lipase with its fatty acids, the influence of trypsin is illustrated. This induced ferment production explains in part the "intense resistance" and natural and acquired immunization. More than one ferment, with its activators or coenzymes, with removal of inhibiting factors, is thus concerned in the defence—for instance (as I suggested in 1905), the glycolytic. The fatty acids themselves are protective; but, whatever the reason, it is a fact that considerable alteration in the metabolism of fats and lipoids occurs in cancer. The part played by macrophages (E. Goldmann, 1912) involved not only suppression of a second growth, but also ferment action on fats and glycogen, as seen in the first stages of tissue-cell formation—for example, repair of wounds.

I have already trespassed too much on your space, and I will now conclude. The results of my researches bring cancer into a wider group of diseases. They provide additional causal considerations, and indicate methods of prevention and treatment.—I am, etc.,

London, April 6th J. A. SHAW-MACKENZIE, M.D.Lond.

SIR,—Having read in your issue of February 28th a notice of Dr. Barbara Holmes's book, *Cancer and Scientific Research*, and, later, the book itself, I wish to discuss briefly two of its teachings. One of these is implied or expressed in various passages—for example, on page 66. It amounts to a premise to the effect that the term "epithelioma" applies only to certain malignant lesions. It is completely opposed to the histology of molluscum contagiosum, which is a pure epithelioma and a benign one. When I taught pathology I used to demonstrate the structure of simple or benign tumours before that of the more complex malignant tumours. In this connexion yet again would I state with assurance that more help towards recognition of the immediate causal agents of common human cancers is to be gained by personal practical work on molluscum than is to be found in any "scientific" volumes.

The other doctrinal point I would refer to occurs on page 112. It runs: "This tumour (granuloma, not a cancer) establishes itself by an infective process—that is, by transformation of normal connective tissue cells—and not by proliferation of the cells introduced." Here I read "sarcoma" for "cancer," making the meaning more definite. The lesion in question is the infective genital tumour of dogs.

Although the point is of the greatest importance, it need not be discussed at length here because the author supplies its refutation by referring (p. 113) to the fact that a transplanted mouse carcinoma sometimes changes into a sarcoma by "causing the surrounding connective tissue to become malignant." This means that ordinary connective tissue cells, mother cells of granulation tissue or granuloma, are so "influenced" that they multiply rapidly, thereby producing a granuloma, which, in these mice, is a sarcoma. Exactly the same is true of the infective genital sarcoma of dogs, of which I published a detailed account in 1908 (*Protozoa and Disease*, Part II, Chapter XV).—I am, etc.,

London, W., April 18th. J. JACKSON CLARKE.

BLOOD PRESSURE AND LIFE ASSURANCE

SIR,—I have before me a medical examination form issued by an important life assurance office, with a special memorandum to medical examiners with regard to blood pressure estimation. The company is "trying to get as accurate blood pressure records as possible in order to compile statistics which will undoubtedly be valuable." The records obtained, however, will be of very doubtful value, because the examiner is instructed to take the diastolic pressure as that point on the descending scale, by the auditory method, at which all sounds disappear. It is nearly twenty years since MacWilliam and his co-workers showed that that point does not indicate the diastolic pressure, but that the reading should be taken when the clear sounds suddenly become muffled. This work was incorporated into standard teaching of physiology and clinical medicine many years ago. In the majority of cases the correct point is quite well defined, and there is no difficulty in demonstrating it.

At post-graduate medical courses one has found, both as a student and as a teacher, that practitioners are not so familiar with the technique of this important clinical estimation as one would have expected, but it is distinctly surprising to find such an error in a memorandum issued by an insurance company. A very good description of the correct method is to be found in *Recent Advances in Medicine*, by Beaumont and Dodds, though it is hardly a "recent" advance.—I am, etc.,

Maymyo, Burma, March 17th. GEORGE R. MCROBERT.

VACCINE DOSAGE

SIR,—In my letter pleading for greater uniformity in the dosage of autogenous vaccines, I took it for granted that it would be understood that I was, of course, referring to cases of a strictly analogous character. Otherwise my complaint would have been completely pointless, for the very obvious reasons which Dr. Shera is at pains to suggest. The cases to which I referred were entirely comparable. Each was an adult; each was suffering from

a chronic infection due to a similar streptococcal strain; each was ordered a first course of autogenous vaccine, prepared from non-detoxicated organisms. But here the analogy comes to an abrupt close, for whereas the commencing dose in each case was fixed, as usual, at 0.1 c.cm., the strength of streptococci ordered by the four experts varied in the proportions of 1, 100, 2,000, and 4,000, each pathologist justifying his dosage by results derived from numbers of similar patients so treated.

It seems strange that at a time when considerable uniformity has been reached in the dosage of prophylactic vaccines, so wide a diversity should still be possible in the therapeutic use of this valuable form of treatment; and though Dr. Shera may consider that my case is a weak one, I would again urge the claim for a more accurate study of reactions, and for greater co-operation, not only between pathologist and clinician (a point on which I am in hearty agreement), but also between pathologists themselves.—I am, etc.,

HAROLD BALME, M.D., F.R.C.S.

Lingfield, April 19th.

THE CANFIELD OPERATION

SIR,—Mr. Aldington Gibb does not state whether he has tried the Canfield operation and found it wanting. I have tried it, and have found it followed by an extraordinarily rapid cessation of the discharge in cases in which the ordinary intranasal operation had failed. The fact is unquestionable. My explanation is only hypothetical.—I am, etc.,

JAMES DUNDAS-GRANT.

London, April 20th.

BIOGRAPHY OF MARGARET McMILLAN

SIR,—I have been entrusted with the task of writing a record of the life and work of the late Margaret McMillan. It will assist materially if any of your readers will send to me any important letters, papers, or pamphlets they may possess. Personal memories would be most helpful. All documents will be returned in due course.—I am, etc.,

ALBERT MANSBRIDGE.

38, High Oaks Road, Welwyn Garden City, Hertfordshire, April 21st.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

This week the House of Commons read the Sunday Performances (Regulation) Bill and the Housing (Rural Workers) Amendment Bill a second time. Other business included the Widows', Orphans', and Old Age Contributory Pensions Bill, making a slight extension of the existing Act; also the Mining Industry (Welfare Fund) Bill and the committee stage of the Representation of the People Bill. The Budget is due to be introduced on Monday, April 27th.

In the House of Lords, on April 21st, consideration of the report of amendments on the Pharmacy and Poisons Bill was postponed until April 28th.

Ministry of Health Vote

The debate on the Ministry of Health vote, on April 14th (reported last week), was concluded by Miss LAWRENCE. She said that, though the figures were not yet to hand, every indication which they had pointed to the fact that 1930 was an exceptionally healthy year. Infant mortality had sunk to the lowest figure ever known, and was now at the figure of 60. The claims of the approved societies showed a considerable rise for the first quarter of 1929, which was marked by the influenza epidemic. The claims were, in round figures, 15½ in 1928, and 17¾ in 1929—due mainly to the influenza epidemic—and they were down now to rather over 15½. Cancer, unfortunately, was an exception to the general rule that 1930 had been an extremely good year. They had been told that the doctors objected to changes in the regulation which extended the period during which a patient might not change his doctor. But here there was ignorance. A doctor, if he chose, could let his patient go at any minute he liked.

Dr. FREMANTLE, interposing, said that his point was that the doctors objected to the change of regulation that had been made, whether it affected them personally or not. Doctors did not always look at things from their personal point of view, but from that of the public.

Miss LAWRENCE said that if a practitioner desired to let his patient go he could do so at once. Members of the medical profession had discretion in the matter. As to the report on bovine tuberculosis, she hoped that that useful piece of work would be published in the course of a few days. Referring to what had been said with regard to the sorting of casuals, Miss Lawrence said that the Ministry found that no less than 15 per cent. of the samples taken were mental deficients. Among these, she was horrified to say, were 800 men and women who were insane—poor, crazy old people, running about without anyone to care for them. The Ministry had given instructions that there should be a periodical medical examination, and had asked the local authorities, whenever it was possible, to conduct their examinations on the same day, to avoid examining the same people over again, and they hoped to get off the roads these poor, unfortunate, crazy and semi-crazy people, who ought to be in lunatic asylums.

Sweepstakes for Hospitals

Mr. Clynes was asked by Sir WILLIAM DAVISON, on April 20th, a question concerning the alleged falling-off of subscriptions to British hospitals since the recent Irish Free State sweepstakes. Sir William asked if the Home Secretary would set up a committee to investigate the conditions necessary before permitting lotteries for approved public purposes. Mr. CLYNES replied that he had delayed coming to a decision on this question in the hope that he might receive some definite indication of the attitude of those responsible for the more important charities. Such indication as he had received seemed on the whole adverse. It would be wise to defer a decision for some time longer. There could be no question of legislation this session.

Cerebro-spinal Fever

On April 21st Mr. SHAW informed Mr. D. Somerville that, during the present month, there had been two fresh admissions to hospital at Aldershot for cerebro-spinal fever. At Catterick there had been four admissions this year. At no military centre other than Aldershot and Catterick had there been more than three cases this year, and there had been no epidemic at any military centre, sporadic cases only having occurred. The disease had occurred also among the civil population.

Tuberculin

Miss LAWRENCE, replying on April 20th to Brigadier-General Brown, said that the Minister of Health was advised that the intradermal test was the best form of the tuberculin test under ordinary farm conditions, but that the results obtained could not be relied on unless tuberculin of sufficient potency was used. The Minister was considering the question of the standardization of tuberculin in consultation with the Minister of Agriculture.

Yarmouth Naval Hospital Bill

On April 20th Mr. AMMON, replying to Mr. Scott, said that the Government took full responsibility for the Yarmouth Naval Hospital Bill, which had been passed by the House. Before its introduction full consideration was given to criticisms and suggestions from departments affected, and the Scottish Office, after the fullest discussion, accepted the Bill. Mr. SCOTT then asked Mr. Ammon whether the Board of Control for Scotland was consulted about this matter, and what advice it gave. Mr. AMMON replied that that was a question to be put to the Secretary for Scotland. Mr. E. BROWN asked if, in the debate on the Bill, Mr. Ammon had not stated that the Board of Control had been consulted

and had given advice. If that was not so, ought not the House to know, and the report be published for members' information? Mr. AMMON replied that in that debate he should have said "the Scottish Office." Mr. SCOTT asked if Mr. Ammon was aware that the Board of Control was a separate organization for Scotland, responsible to the Secretary for Scotland. Mr. AMMON replied that the Board of Control was responsible to the House through the Scottish Office.

Housing

Mr. GREENWOOD told Mr. West, on April 16th, that under the five-year programme the London County Council would build 32,570 houses, the metropolitan borough councils 10,860, and Kensington Metropolitan Borough Council 82.

Replying to Mr. Shakespeare on April 16th, Mr. GREENWOOD stated it was estimated that between 450,000 and 500,000 houses would be provided with State assistance in the coming five years, and it was hoped that approximately one-fifth of them might be completed in the first year.

Change of Doctor.—Mr. GREENWOOD told Mr. Albery, on April 16th, that he could not consider amending the new Regulation which restricted the right of insured persons to change their medical adviser.

Optical Appliances for Insured Persons.—Mr. GREENWOOD told Mr. White, on April 16th, that he had no information as to the number of opticians who undertook the supply of optical appliances to insured persons entitled to ophthalmic benefit under the national health insurance scheme. The Regulations governing the administration of this benefit did not provide for the approval of opticians.

Food Standardization.—Mr. GREENWOOD told Major Church, on April 16th, that he was not yet in a position to make any announcement as to the membership of the committee to consider the law on the composition and description, including the fixing of standards and definitions, of articles of food. No "representative scientific bodies" had been consulted about the constitution of the committee, but these bodies would be able to give evidence before the committee.

Institutional Provision for Tuberculosis.—In reply to Mr. Ede, on April 16th, Mr. GREENWOOD said that the officer who recently investigated the prevalence of tuberculosis in South Shields had not made any report on the incidence of this disease in those parts of the borough where the partition of houses into tenements had taken place. Mr. Greenwood added that, at the request of the town council, he had invited a number of local authorities in the north-east of England to send representatives to a conference for the purpose of considering institutional accommodation for the treatment of tuberculosis in that area. It was hoped to arrange for the conference at an early date.

Registration of Blind Persons.—The total number of registered blind persons in England and Wales was 52,727 on March 31st, 1929, the latest date for which official figures are available. According to unofficial figures there were 56,853 registered blind persons on March 31st last.

Vaccination.—On April 21st Mr. FREEMAN asked the Minister of Health what steps his department was taking to give effect to the recommendation of the Rolleston Vaccination Committee, in its recent report, that every public vaccinator should be prepared to carry out a second operative procedure to mitigate the risk of nervous complications after vaccination. Mr. GREENWOOD replied: I cannot find any such recommendation in the report.

Commutation of Pensions.—Sir HERBERT CAYZER asked Mr. F. O. Roberts, on April 20th, whether he would place before the Pensions Commutation Board any cases where the application of retired regular officers for pension had been refused on medical grounds. Mr. ROBERTS replied that, in deciding whether such applications should be recommended to the Board, regard was had to the officer's state of health and expectation of life. Where the Minister's medical advisers considered the case unsuitable on these grounds it was not possible for him to recommend it.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

The following candidates have been approved at the examination indicated:

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY.—*Part I:* G. Maclean, W. S. C. Yuen. *Part II:* P. C. Basu, S. Bradbury, Isabella M. G. Butler, T. V. L. Crichlow, J. Grieve, K. H. Hallam, Elfrida L. G. Hilton, C. C. Kapila, Ethel E. A. Pepper, H. W. A. Post, R. Rekhi, F. P. Schofield, I. C. C. Tchaperoff.

UNIVERSITY OF LONDON

A University studentship in physiology, value £100, is offered to a student qualified to undertake research in physiology. Particulars can be obtained from the Academic Registrar, to whom applications must be sent by May 31st.

A course of six advanced lectures on special sense physiology will be given at University College, Gower Street, W.C.1, by Dr. R. J. Lythgoe, on May 7th, 14th, and 28th, and June 4th and 11th, at 5 p.m. Admission is free, without ticket, to the lectures, which are addressed to students of the University and others interested in the subject.

UNIVERSITY OF BIRMINGHAM

A course of five lectures on some correlations between general and psychological medicine will be given by Sir Hubert Bond of the Board of Control in the Medical Faculty Buildings on May 13th and 27th, and June 10th, 17th, and 24th, at 4 p.m.

Professor W. Blair Bell of Liverpool will deliver the Ingleby Lectures on May 21st and June 4th; his subject will be maternal disablement.

The Clinical Board of the University has arranged a course of post-graduate demonstrations from April 28th to July 24th. Admission cards are issued on payment of £2 2s.

The Services

MEDICAL DIRECTOR-GENERAL R.N.

Surgeon Rear-Admiral Reginald St. G. S. Bond, C.B., M.B., C.M., F.R.C.P., F.R.C.S.Ed., has been appointed to succeed Surgeon Vice-Admiral Sir Arthur Gaskell, K.C.B., F.R.C.S., as Medical Director-General of the Navy, on July 1st.

HONORARY SURGEON AND PHYSICIAN TO THE KING

Major-General H. Boulton, C.B., C.B.E., I.M.S., has been appointed Honorary Surgeon to the King, vice Major-General F. H. G. Hutchinson, C.I.E., I.M.S.(ret.); and Colonel C. W. F. Melville, Honorary Physician to His Majesty, in succession to Brevet Colonel S. R. Christophers, C.I.E., O.B.E., I.M.S.(ret.).

INDIAN MEDICAL SERVICE DINNER

The annual dinner of the Indian Medical Service will be held at the Trocadero Restaurant on Wednesday, June 17th. Colonel R. A. Needham, C.I.E., D.S.O., has been invited to take the chair. Tickets and all particulars may be obtained from the joint honorary secretary, Major Sir Thomas Carey Evans, *M.C.*, I.M.S. (ret.), 31, Wimpole Street, W.1.

DEATHS IN THE SERVICES

Major Jehangir Hormusji Oonvala, Indian Medical Service, died of heart failure at Razmak, Waziristan, on February 1st, aged 43. A member of the Parsi community he was born on September 13th, 1887, and was educated at Bombay University, where he graduated as L.M.S. in 1910. Soon after the war began he took a temporary commission as lieutenant in the I.M.S., on October 18th, 1914, became temporary captain a year later, and on March 15th, 1920, received a permanent commission, being ranked as captain from July 17th, 1916, and was promoted to major on April 18th, 1926. In 1927 he took the diploma in tropical medicine and hygiene, with distinction, of the London School of Tropical Medicine, and in 1928 obtained the same diploma from the London Colleges. He served in the war of 1914-18, and for the last two years held the appointment of deputy assistant director of pathology of the Waziristan district, on the north-west frontier of India.

Obituary

T. DYKE ACLAND, M.D., F.R.C.P.

Consulting Physician to St. Thomas's Hospital and the Brompton Hospital for Diseases of the Chest

We regret to announce the death, at his home in Bryanston Square, W., on April 16th, of Dr. T. Dyke Acland, for many years a prominent and greatly respected member of the medical profession in London.

Theodore Dyke Acland was the third son of Sir Henry Acland, Bt., F.R.S., regius professor of medicine at Oxford from 1858 to 1894. The Aclands are a well-known Devonshire family, members of which, from generation to generation, have taken an active part in public affairs. He was born on November 14th, 1851, and from Winchester went up to Christ Church, Oxford. He gained a first class in the honour school of natural science in 1874, and entered as a medical student at St. Thomas's Hospital. Later he studied at Leipzig and Berlin when holding the Radcliffe Travelling Fellowship. He graduated M.A. in 1876, M.B. in 1880, and proceeded M.D. in 1883. After holding the posts of house-physician, house-surgeon, and resident accoucheur at St. Thomas's Hospital, he went to the City of London Hospital for Diseases of the Chest as resident clinical assistant.

Acland was one of the medical officers sent by the Foreign Office from England to Egypt during the serious cholera epidemic in July, 1883, and he was then attached as physician to the Military Cholera Hospital. After this he served as principal medical officer to the Egyptian Army. He received Egyptian decorations for his services at this time, and was thanked by the Khedive His experience in Egypt in the 'eighties led to his appointment as a member of the Egypt and Sudan Medical Board in London; and in 1906 he was the first assessor of examinations at the Cairo Medical School

Soon after returning to England from Egypt, Acland became pathologist and assistant physician to the Hospital for Consumption, Brompton, and he was also for some years on the honorary staff of the West London Hospital At St. Thomas's Hospital he served for many years as assistant physician and full physician, and on his retirement from the active staff was elected consulting physician and a member of the governing body. He was also consulting physician to King Edward VII Sanatorium, Midhurst, and a visiting member of the committee of King Edward's Hospital Fund. He was in great demand as an examiner in medicine, and acted in this capacity for the Universities of Oxford, Cambridge, Manchester, and Leeds, as well as for the English Conjoint Board and for the Indian Medical Service. For some years he had a seat on the Board of the Faculty of Medicine at Oxford. He became a member of the Royal College of Physicians of London in 1884, and was elected to its Fellowship in 1889. He held many executive offices in the College, including that of Censor in 1913–15.

His principal publications were the articles on actinomycosis, vaccines, and subphrenic and other forms of peritoneal abscess in Allbutt's *System of Medicine*. He contributed several papers to the *St. Thomas's Hospital Reports*, of which he was at one time editor. He also edited in 1894 the published writings of his father-in-law, Sir William Gull, which had been prepared but not completed by his father, Sir Henry Acland. The book is in the New Sydenham Society's publications; it is an interesting account of a great physician, which can be read with profit by any medical man. At the Annual Meeting of the British Medical Association held in Dublin in 1887 he was honorary secretary of the Section of Pathology and Bacteriology; at Leeds in 1889 he was honorary secretary of the Section of Medicine; and at Oxford in 1904 vice-president of the Section of Medicine; he represented the Marylebone Division in the Representative Body, 1912–13, was a member of the Metropolitan Counties Branch Council in 1913, and vice-president of the Branch in 1915.

During the war he held a commission as lieutenant-colonel, R.A.M.C.T., and acted as consulting physician to the London district, and to the special surgical hospital at Shepherd's Bush, which was afterwards taken over by the Ministry of Pensions.

We are indebted to Dr. H. G. Turney, consulting physician to St. Thomas's Hospital, for the following appreciation:

The death of Theodore Dyke Acland leaves a gap in a wide circle of friends who come, not only from the medical profession, but from every walk in life, and his loss will be deeply felt by them, though their opportunities of meeting him have been sadly restricted during recent years, first by the prolonged illness of his wife, and of late by his own failing health. To those who have missed him these vagrant reminiscences may make some appeal.

The picture of Acland that comes to the mind's eye is that of exuberant vitality and joy of living, of a man who radiated geniality and kindliness wherever he went. And yet, even in his youth Acland had something of the ancestor about him which fitted in well with a growing tendency towards stoutness and a ready laugh of Pickwickian jollity. His appreciation of humour was of the keenest, and this no doubt helped to make him a delightful raconteur and after-dinner speaker. His hospitality was overwhelming, and as a host he came very near perfection. But if certain traits made one think of Pickwick, there was one which brought to mind another lovable hero of romance. He had a burning passion for taking up the cudgels on behalf of anybody who seemed to him to be the underdog, and many were the cases of hardship or injustice which he saw righted. But unfortunately there were times when the underdog was quite deservedly in that position, or when he was not

really an underdog at all, but only pretending to be, and then there was a danger that he might enlist Acland's generous impulses of protection. This did happen sometimes, and resulted in strained relations between some very good friends. There are possibly even Government officials who might tell grievous tales of what they suffered at Acland's hands in his defence of dissatisfied pensioners or ex-soldiers, and it is doubtful if even Government officials were guilty of all the obstinacy with which Acland was inclined to credit them in his narration of his victory. But no picture of Acland would be honest, much less complete, if no mention were made of this element of contentiousness in his nature. There was nothing dour about it, and he certainly never bore malice. It was just an aspect of his quixotism.

Acland's professional life was spent chiefly at St. Thomas's and Brompton. His interests, of course, were mainly centred about pulmonary tubercular disease, and in this domain he became a recognized authority. He was immensely popular with his students at St. Thomas's, and formed a lifelong friendship with many of them. But as a teacher he fell short of complete success, in spite of the infinite pains he took; this was due, probably, to a certain lack of concentration and perspective which he was never able to overcome.

In these remarks Acland has been described as if he belonged solely to St. Thomas's among the teaching hospitals. And so in the strict sense he did. But he might also be quoted as an example of the old tie that binds together St. Thomas's and Guy's. He had an intense admiration for, and friendship with, Sir William Gull, the great Guy's physician. He edited his works, and Gull's only daughter became his wife. The union was an ideal one, and when it was sundered by death two years ago the light went out of his life for ever. No words can express the beautiful devotion with which he unflaggingly tended her through the many weary years of her illness.

Acland was a profoundly religious man, not only in the sense that he maintained religious observances in his house, but as describing the warp and woof of his thought. He accepted the doctrines of religion with a childlike simplicity, which never faltered and never called for the buttress of an argument.

He changed very little with the process of time. Even after his wife's death, when he was a sad man waiting for the end, he still kept on a mask of jollity, though tears were never far from the laugh that rang out as an echo of the past.

Mr. HENRY PERCY DEAN, consulting surgeon to the London Hospital and the Queen's Hospital for Children, died at his home in Bedford Park, London, on April 14th, at the age of 66. A son of the late Henry Dean of Rosary Gardens, S.W., he was born on September 19th, 1864, and studied medicine at University College, London, where he had a brilliant student career, winning a scholarship and gold medal in physiology and surgery, and an exhibition and gold medal in anatomy. He graduated B.Sc.Lond. in 1884, M.B. and B.S. with honours in 1888, and obtained the M.S. degree and the Fellowship of the Royal College of Surgeons of England in the following year. Soon afterwards he was elected to the surgical staff of the Great Northern Hospital in Holloway Road (now the Royal Northern Hospital), and he served for many years as assistant surgeon and surgeon to the Queen's Hospital for Children, Hackney Road. He was elected assistant surgeon to the London Hospital and teacher of operative surgery in 1892, becoming full surgeon in 1909; he retired from the active staff of the hospital in 1913, when he was appointed consulting surgeon. Mr. Dean was elected a Fellow of University College, London, in 1890.

Dr. WILLIAM GRAY of West Hartlepool died on April 15th at the age of 60, after several years of indifferent health. He was educated at Blairlodge and the University of Edinburgh, graduating M.B., C.M. in 1892, and M.D. with honours in 1896. Almost the whole of his working life was spent in general practice at West Hartlepool. During the war he acted as civilian medical officer to the 3rd Yorks and other regiments, and was afterwards recruiting medical officer and chairman of the local pensions medical board. When the Cameron Hospital was opened at West Hartlepool in 1905, Dr. Gray was appointed honorary surgeon, and the establishment of an orthopaedic department was largely due to his efforts. For more than thirty years he gave first-aid lectures to railwaymen and others, and often acted as judge in ambulance competitions. In recognition of his work in this field he was made an officer of the Order of St. John of Jerusalem in England.

Medico-Legal

PACK LEFT IN ABDOMEN AFTER OPERATION

APPEAL AGAINST VERDICT OF "NEGLIGENCE"

In the Court of Appeal, before Lords Justices Scrutton, Greer, and Slesser, on April 15th and following days, the appeal was heard of Dr. John Dunlop of Abercarn, Newport, Mon., from a verdict and judgement against him in an action tried by Mr. Justice Branson and a special jury at the last Shropshire Assizes. The action, which was brought under Lord Campbell's Act, was by Mrs. James, widow of an assistant bank manager, who alleged negligence against Dr. Dunlop during an operation on her husband, as the result of which a surgical pack was left in his body, necessitating a further operation three months later, his death following within a few days. The jury found negligence proved, and awarded the widow £1,500, with £500 for her child, and £100 special damages. Against this verdict Dr. Dunlop now appealed, pleading that it was against the weight of evidence, and asked for a new trial.

The appellant, Dr. Dunlop, was represented by Mr. Stuart Bevan, K.C., the Hon. Sir R. W. Coventry, K.C., and Mr. H. E. Dickens, instructed by Messrs. Hempson, acting on behalf of the Medical Defence Union. Mrs. James was represented by Mr. J. W. Morris and Mr. Gilbert Griffiths, instructed by Mr. Malwyn Jenkins.

Mr. Stuart Bevan said that the operation, which was intended for removal of the gall-bladder (though in the event only a number of gall-stones were removed), took place on December 11th, 1928, at a voluntary hospital. The patient remained ill, and on March 20th, 1929, he having returned home in the meantime, a second operation was performed by a Dr. Burrell, when the pack was discovered; it had set up a fistula, from which the patient died on March 27th. It was admitted that the pack was left in the body, but negligence was denied. The negligence alleged was twofold. The first ground was that the defendant had left this pack of towelling in the body. The answer made by Dr. Dunlop was that it was the duty of a skilled nurse to check the packs and swabs as they were removed. A good deal of medical and surgical evidence was tendered at the assizes to the effect that it was no part of the duty of the surgeon to count the swabs, either those inserted or those taken out. In practice, and in the interests of the patient, this task should be left to the special nurse detailed for the purpose. Only if the nurse reported that a swab was short did the surgeon make a detailed and perhaps a prolonged search, but this might endanger the life of the patient. The second ground on which negligence was alleged was that as the patient lived for three months after the operation, and was seen by Dr. Dunlop, the doctor was negligent in not discovering from the patient's condition that the pack was embedded among the intestines. On that allegation, however, the verdict was in Dr. Dunlop's favour. It could scarcely have been otherwise, because other doctors were attending the patient after the operation, and failed to suspect the presence of any foreign body. But on the first ground a verdict of negligence was returned, although it was the common and necessary

practice of all operating surgeons to leave the counting of packs and swabs to a nurse.

Questions were asked by their lordships as to the size and number of the packs. Mr. Bevan said that the pack which had been buried (exhibited in court) was 8 inches by 10 inches. Neither Dr. Dunlop nor a Dr. Sullivan, who had assisted him, could remember at this distance of time how many packs were used, but the general evidence was that the number of packs in an operation of this kind varied from three to five, and Professor Gamgee, who had given evidence for the defendant, put it as high as occasionally seven or eight. The evidence showed that Dr. Dunlop, at the operation, asked the question, "Are all the swabs out?" and he heard a female voice answer "Yes," but he could not swear that it was the voice of the sister appointed to count the swabs. There were also in the theatre the matron, who was keeping count of the instruments, and two probationers, but their evidence was not definite, and the swab sister was not called. She was a certificated nurse, and had worked for Dr. Dunlop for eighteen months. To the question, "Did defendant receive an assurance from the swab sister?" the jury replied, "Evidence not satisfactory."

Lord Justice Greer: Is the surgeon not bound, when he extracts swabs or packs, before he receives any information from the nurse, to exercise reasonable care in such extraction?

Mr. Bevan: To take reasonable care, but not to probe under the intestines to find any swab that might be there.

Lord Justice Greer: It does not follow from the fact that there is somebody to check that he cannot be guilty of negligence in not getting them out.

Mr. Bevan: If there were no system of counting, a search would have to be made which might endanger the life of the patient.

Lord Justice Greer: If only three swabs were used the surgeon would know quite easily without asking the nurse whether all were out. These are packs of very large size.

Mr. Bevan went on to say that some criticism had been made of the operating doctors that they were negligent in using packs without tabs to which forceps were attached, but it appeared that there was in the medical profession a great difference of opinion as to the desirability of this procedure, and Dr. Burrell, who gave evidence for the plaintiff, admitted that tabs were not an absolute safeguard.

Lord Justice Greer: If the surgeon knew that he had put four swabs in and had reason to think he had only taken three out, he would have to do something to find the fourth.

Mr Bevan: He may start the operation with four, but in the course of the operation some are taken out and others put in The assistant surgeon may be also putting in packs. The number of packs could no more be remembered by the doctor than the number of pages of a brief by a barrister.

After further argument as to the possibility of the pack concealing itself under the intestine, Lord Justice Scrutton said that what had evidently puzzled the jury was that this particular swab, "after a little trip, returned to its original home," for it was found by Dr. Burrell at approximately the place where it had been inserted.

Sir Reginald Coventry also addressed the court on behalf of Dr. Dunlop He said that the system of checking the swabs and packs was a matter which had been debated at medical meetings for years. If it was such an easy thing to keep count, why had there been so much discussion upon it? It was admitted by the experts that "the undiscovered swab is the bugbear of abdominal surgery."

Lord Justice Scrutton: I do not wish to say anything about the profession of medicine that I would not say of the Bar, but is every surgeon on every occasion careful? I am sure that every counsel on every occasion is not, nor every judge. You are setting up a standard for the medical profession that it can never make a mistake.

Sir R Coventry: They make every endeavour to be careful.

Lord Justice Slesser: In many dangerous operations the surgeon has to tie arteries. It is his business, I suppose, to remember the number of arteries he has tied.

Sir R Coventry: He is able to see the arteries. It is because of his duty to watch the arteries, stop bleeding points, and make the most careful incisions, that he is relieved of the other task of counting swabs, which is entrusted to the nurse. Supposing we did not carry out that system, would not the patient have a complaint against us? Supposing Dr. Dunlop had refused to accept the word of the nurse, and the patient had died under the protracted operation, would not the widow have said, "You have a recognized practice in medicine which you did not follow"?

The evidence with regard to the assurance given by the nurse was read. Sir R. Coventry said that only one of the three doctors present at the operation was prepared to swear that the nurse answered in the affirmative. Dr. Dunlop himself having said that he heard an affirmative answer in a female voice, though he could not swear that it was that of the nurse, but all four witnesses—the two surgeons, the anaesthetist, and the matron attending to the instruments—agreed that the question was put, and the inference was that an answer was given.

Mr. Morris made briefly some submissions on behalf of the plaintiff. He said that a body of evidence had been given in the court below as to the practice of surgeons in operations generally, but the only witness who confined his evidence to what was done in operations on the gall-bladder was Dr. Burrell, who gave evidence for the plaintiff. He also commented on the absence of evidence as to any definite assurance from the nurse that the swabs were out. Evidently nobody —neither doctors nor nurses—had a clear recollection of what took place at this particular operation, and they spoke of things as having occurred because in cases of a similar kind it was usual for them to occur.

Judgement: Appeal Dismissed

Lord Justice Scrutton, in giving judgement, said that this was undoubtedly an important case for the parties and to some extent for the medical profession. The substantial question was the contention that the verdict, though there was some evidence, was so far against the weight of the whole evidence that the findings of the jury ought to be set aside and a new trial ordered. The test the court had to apply in such a case had now been well established. Where there had been a jury the Court of Appeal was not exercising the same function as when hearing an appeal from a judge. In the case of an appeal from a judge the court re-heard, and had to make up its mind what it would have done. But with a jury the question was quite different. The jury was the tribunal which had to come to a conclusion if there was evidence on which it could reasonably do so. It was no ground for setting aside the verdict of a jury that the Court of Appeal thought that it might have come to a different conclusion. It could only interfere if, on the whole evidence, the verdict was such that a reasonable jury ought not to have arrived at it. It must be very nearly a perverse verdict, in the language of Lord Selborne, before the Court of Appeal interfered. No fault could be found with the way in which the learned judge (Mr. Justice Branson) had summed up the case to the jury. He had explained to them that doctors did not guarantee success in operations, and he had explained the measure of care and skill which a doctor owed to his patient, not such skill as the most eminent man in the profession would show, but the ordinary average skill of a practitioner trained in the profession he undertook. Lord Justice Scrutton continued:

"A well-recognized operation was carried out. It was an essential part of the operation to wall off the gall-bladder by the insertion of certain crumpled-up pieces of towelling, or sometimes of gauze. Usually the wall would be made of three bundles of such material. It is quite clear that the only person who puts those things in and selects the place where they shall be is the doctor. He puts in not a large number, but generally three. Any jury would be impressed by the substantial character of a crumpled-up piece of towelling. It is a set part of the operation for the doctor, and the doctor only, to take out the three or more big pads of towelling he has put in. He must know where he has put them, and it is his business to take them out. The jury answered 'No' to the question 'Did the defendant make such search in the wound as was reasonable and necessary?' Is that an answer which the jury might not arrive at reasonably? My impression is that any jury who had felt that towelling and seen the size of it would come to the conclusion that it was careless not to have taken it out. Dr. Dunlop's case was that the pack might be put in at the commencement of the operation and it might move away. I cannot say that the jury were wrong if they entirely rejected this theory of the perambulating swab ultimately coming home to rest. There is the evidence given by Dr. Burrell as to where he

found the swab, and the permanent and thick wall by which it was surrounded, showing that it had been there for some time.

"Then comes the more important question: if, in the operation, you put ten swabs into the body, and remove such swabs as you think you have put in, and they are then counted by a competent person, it is said for the defendant that the doctor is quite entitled to rely on the count of a competent person, although competent persons do make mistakes. Before there is any count there is a duty on the doctor. His duty is to put in the necessary swabs according to the set course of the operation, and it is his duty to use reasonable care to put them in the proper place; it is his duty to take them out, and that is independent of any check or count. He is the person who knows where he put them in, and knows also the amount of movement that might be reasonably expected. I cannot help thinking it is fairly slight. The doctor's plea is, 'If I get an assurance from a competent nurse that all swabs put in have been checked out I need not myself do any further search.' The jury were asked, 'Did the defendant receive an assurance from the nurse that all the swabs were removed?' and to that the answer was, 'Evidence not satisfactory.' I read that answer to mean that they were not satisfied on the evidence that the defendant did receive such an assurance. If that answer stands there is an end of the case. There were two highly qualified nurses assisting in the operation, one in charge of the sterilized instruments and the other in charge of the swabs and packs. The two nurses were standing together. The nurse who is supposed to have given the assurance was not called, either at the inquest or at the trial of this action. The jury are entitled, in my view, reasonably to attach considerable importance to the fact that the lady who was said to have given the assurance was not called. The other nurse said, 'I heard the question asked, but I cannot remember that I heard any answer.' Can one possibly say that the jury might not reasonably find themselves not satisfied that the assurance was given to the doctor? . . . The language in which Dr. Dunlop gave evidence at the trial is such that the jury might have thought, 'The doctor does not really remember, but because it is the regular thing in operations for such an assurance, he assumed that such a thing as ought to have happened did happen.'"

The jury had assessed damages in a way distinctly favourable to the doctor; they might easily have given a larger amount. Taking all these things together, he could not possibly say that the verdict was such that the present Court ought to interfere. The appeal must be dismissed.

Lord Justice Greer said that he had come to the same conclusion. It was quite clearly part of the operation to insert the packs, and equally part of the operation to remove them. This involved a search after the operation was over. The fact that counting might be exercised by some other people did not absolve the doctor from the necessity of making some reasonable search before he put any question to the nurse with regard to the count. The duty of the nurse to count could not absolve the surgeon from his duty to exercise reasonable care. It was possible that the moving proclivities of packs had caused this pack to make a circuit of the intestines and come back approximately to the place of its insertion, but judges and juries had to judge by the rules of probability, and the jury might have reasonably felt that it was highly improbable that the swab took the course suggested by the defendant's witnesses as an explanation. He agreed that there was nothing which justified the Court in setting aside the verdict as against the weight of evidence.

Lord Justice Slesser also concurred. All the doctors were agreed that it was proper that in such an operation there should be a nurse appointed to count the swabs before and after, and Dr. Dunlop did appoint a competent nurse. But Dr. Burrell had said, "This is no more than a precaution to corroborate the surgeon's knowledge," whereas the doctors for the defendant rather indicated that the nurse's assurance was the essential matter. In so far as the defendant relied on the assurance of the nurse, the jury are entitled to take into account that this nurse, who could definitely have said she had or had not counted the swabs, was not called, and that the other nurse could make no reply. In these circumstances it became immaterial to consider whether there was or was not a general practice of doctors to rely upon the assurance of the nurse, as the defendant had failed to satisfy the jury that he did rely on such assurance, and the case rested entirely on its own peculiar circumstances. The appeal must be dismissed.

Medical News

The annual London dinner of the University of London Medical Graduates Society will be held on Tuesday, May 12th, at the Langham Hotel, Portland Place, W.1, at 7 for 7.30 p.m., under the chairmanship of the president, Sir John Rose Bradford, Bt. Lord Dawson, P.R.C.P., Lord Moynihan, P.R.C.S., and the Vice-Chancellor will be the guests of the society. Medical graduates of the University who are not members can obtain dinner tickets on application to the secretaries of the society, 11, Chandos Street, Cavendish Square, W.1, not later than May 8th.

The president and council of the Medical Women's Federation will hold a reception in the Great Hall of the British Medical Association House, Tavistock Square, on the evening of Thursday, May 7th.

The annual general meeting of the Section of Surgery of the Royal Society of Medicine will be held on Wednesday, May 6th, at 8.30 p.m. A discussion on the surgical treatment of simple ulcers of the body of the stomach will be opened by Mr. A. J. Walton and Mr. G. Gordon-Taylor. The annual provincial meeting of the Section will be held in Manchester on Wednesday, June 10th.

The reconstruction of the Royal Institution, in Albemarle Street, will be celebrated on the evening of Wednesday, May 6th, by a house warming, when guests will be received by the president, Lord Eustace Percy, and Managers.

At a meeting of the Paddington Medical Society, held on April 14th, an address entitled "The work of the tuberculosis dispensary" was delivered by Dr. R. S. Walker (tuberculosis officer, Paddington). The dispensary was open to inspection, and *x*-ray films, pictures, and models were shown.

At a meeting of the Eugenics Society on Tuesday, April 28th, at 5.30 p.m., in the Rooms of the Linnean Society, Burlington House, W.1, Dr. Aubrey J. Lewis (Maudsley Hospital) will read a paper on genetic problems in psychiatry. All interested in this subject are invited to attend. Tea, 5 o'clock.

The annual general meeting of the London and Counties Medical Protection Society will be held at Victory House, Leicester Square, W.C.2, on Wednesday, April 29th, at 4 p.m.

The annual meeting of the Medical Mission Auxiliary of the Church Missionary Society will be held in the Central Hall, Westminster, on Wednesday, May 6th, at 7 p.m. Tickets of admission may be obtained from the superintendent, Loan Department, Church Missionary Society, Salisbury Square, E.C.4. There will be a small number of reserved seats at 1s. each.

To mark the twenty-fifth anniversary of the opening of the Infant Welfare Clinic of St. Marylebone General Dispensary, a meeting will be held at 30, Marylebone Lane, Cavendish Square, W., on April 29th, at 5 p.m., with the Mayor of St. Marylebone in the chair. Addresses will be given by Miss Susan Lawrence, M.P., by Dr. Charles Porter, and by Dr. Eric Pritchard, who has been associated with the clinic since its inception.

An intensive course in radiotherapy, especially in its relation to malignant disease, arranged by the National Post-Graduate School of Radiotherapy, will be held at the Radium Institute, Riding House Street, W.1, commencing Monday, June 1st.

Particulars of the lectures and demonstrations arranged for next week by the Fellowship of Medicine will be found in our Diary of Post-Graduate Courses, published in the *Supplement* at page 160. The following special courses begin on April 27th: in diseases of children, at the Hospital for Sick Children; in diseases of infants, at the Infants Hospital; in psychological medicine, at the Maudsley Hospital; and in diseases of the ear, nose, and throat, at the Central London Throat, Nose and Ear

Hospital. Syllabuses and tickets of admission may be obtained from the Fellowship of Medicine, 1, Wimpole Street, W. Courses beginning in May include dermatology at the St. John's Hospital, diseases of the chest at the Victoria Park Hospital, ophthalmology at the Royal Eye Hospital, and special evening lectures in preparation for the M.R.C.P. examination at the Medical Society, 11, Chandos Street, W.

A course on the surgery of children will be held at Bordeaux from June 1st to 9th, and on orthopaedics from the 15th to 20th, under the direction of Professor Rocher. The fee is 200 francs. Further information can be obtained from the secretary of the Bordeaux Faculty of Medicine.

A post-graduate course on the diagnosis and treatment of allergic diseases will be held in German at the pharmacotherapeutic institute of Leyden University from May 26th to 28th. The lecturers will be Professor Storm van Leeuwen of Leyden, Professor Rost of Freiburg, and Dr. Dekker of Wald. .

The seventeenth annual conference of the National Association for Prevention of Tuberculosis will be held at Margate from June 25th to 27th. The subject of the conference will be the protection of the child from tuberculosis, and the opening speakers include Sir Robert Philip, Dr. Eugene L. Opie of the United States, who will consider the varying manifestations of tuberculosis at successive periods in childhood, and Dr. Letitia Fairfield, who will deal with the administrative outlook. A discussion will be held on the protection of the child from tuberculosis at birth and during its earliest years of life, and there will also be discussions on its protection during pre-school and school years. The conference is open to all interested in tuberculosis, on payment of the fee of £1 1s. Further information may be obtained from the secretary, N.A.P.T., Tavistock House North, Tavistock Square, W.C.1.

Applications for grants from the Asthma Research Council should be made before May 16th. They should be addressed to the secretary, Asthma Research Council, c/o. King's College, Strand, W.C.2, and accompanied by a detailed statement of the proposed research and the qualifications of the worker.

The second International Hospital Congress will be held in Vienna from June 8th to 18th, when the following subjects will be discussed: the cost of hospital construction, by Distel of Hamburg; the role of the hospital nurse, by Reimann of Geneva; hospital terminology, by Wirth of Frankfurt; hospital legislation, by Harper of Wolverhampton; out-patient departments, by Corwin of New York; patients' diets, by von Noorden of Vienna; and neurology and psychiatry in general hospitals, by Alter of Dusseldorf. Further information can be obtained from the general secretary, Professor Tandler, 9, Rathausstrasse, Vienna, I.

A third tour for medical men to the spas and climatic resorts in the North of Spain, to last ten days, is being arranged. The party will leave Santander about the middle of July for Covadonga, Pics de l'Europe, Côte Asturias, Coruña, Santiago de Compostela, Vigo, and other places. It is hoped that certain Portuguese stations may also be visited. The cost from Santander will be 1,200 French francs. For further information and inscription, application should be made to Docteur Mariano Muñoru, Ronda del Condo Duque No. 4, Madrid. The list will close on or before May 15th.

The issue of *La Medicina Ibera* for April 4th contains an account of the first Spanish Congress of Digestive Pathology, held at Valencia from March 16th to 18th, with portraits of the principal speakers.

In future the *British Journal of Actinotherapy and Physiotherapy* will be published under the title, "*The British Journal of Physical Medicine* (incorporating the British Journal of Actinotherapy and Physiotherapy)." This alteration takes effect from the current month's issue, which forms No. 1 of volume 6.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM* 9861, 9862, 9863, and 9864 (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Medisecra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS

Medical Hypnosis

"E. J. B." (Bristol) wishes to know of a practical course in medical hypnosis, either at any home medical school or a holiday course in Germany.

Wagstaff's Forceps

Dr. A. T. BRAND (Driffield) writes in reply to the query by "Croydonian" (April 18th, p. 692): On pages 215 and 216 of *Clinical Memoranda for General Practitioners*, by Brand and Keith (Baillière, Tindall and Cox, London), will be found a full description of Wagstaff's forceps. The experience of the authors with this admirable obstetric instrument is given, and directions are supplied to distinguish between the upper and lower blades of forceps; also, which should be first applied, and why. The instrument being axis-traction forceps, simple traction is alone necessary. Information is also given as to where the forceps may be obtained.

Chronic Rhinitis

Dr. F. G. GARDNER (Oxford) writes: From time to time I see letters in the *Journal* asking for advice in the treatment of this condition. I am not going to suggest any form of medical treatment, but I do suggest strongly that many of these cases are due to forcible and frequent nose-blowing, which injures the delicate lining of the nose, making it liable to fresh infection. At the same time the trachea, tonsils, the Eustachian tubes, and the accessory sinuses are "sprayed" with infected material from the nose, and so other troubles of the upper respiratory tract are started. "G.P.'s" case seems to corroborate my view. I offer my suggestion to him. Nose-blowing is quite unnecessary, but if it *must* be performed, it should be done gently, and one side cleared and then the other. There is no doubt the nasal secretion has antiseptic properties which, if not interfered with, act as a protection against many forms of infection.

Income Tax

Motor Car Expenses of Assistant

"J. O." acted as an assistant from April 1st, 1930, to February 22nd, 1931. In May, 1930, he bought a car and used it for his work, his principal supplying petrol, all other expenses being met by himself. He asks whether he can deduct certain specified outlay, etc.

*** (1) Nothing can be deducted in respect of the capital outlay incurred in buying the car. (2) Current expenses, including tax and insurance premiums, repairs, cleaning, etc., can be deducted, except as regards any proportion fairly attributable to personal use. (3) He can claim 20 per cent. per annum of the value of the car as at the beginning of the year, less any personal proportion as above

Post-Graduate Course

"G. J. L." was doing a post-graduate course during the months of April, May, and June of 1930, and then took up professional work. Can he deduct, in computing his assessable income, the expenses, fees, books, travelling, etc., during the post-graduate course?

⁂ No. Those expenses were incurred in acquiring additional professional knowledge, and represent essentially an outlay of capital, and consequently cannot be treated as expenses for income tax purposes.

Discount on Prepayment of Income Tax

"I. B. M." inquires whether, in the event of income tax being paid before the due date any discount is allowed.

⁂ The point is covered by Section 159 of the Income Tax Act of 1918, which provides that, as regards tax payable under Schedule D, an allowance can be claimed at the time of payment at the rate of 2½ per cent. *per annum* for the period from the date of payment to the due date. Thus, if £50 is due on January 1st, 1931, and is paid on December 1st, 1930, discount can then be claimed to the extent of 2s. 1d.

Appointment: Travelling Expenses

"O. C. D." holds a public appointment which necessitates a good deal of travelling, and he is allowed 5d. per mile by the local authority "for certain journeys." He regards this as covering the running cost, but not the depreciation of the car. Can he claim an allowance for income tax purposes?

⁂ Yes, provided that he can show that the use of a car of the horse-power and grade employed is necessary for the carrying out of the duties, and also that the 5d. per mile does not cover depreciation. (In computing the depreciation regard would have to be had to the extent to which the car is used for private purposes.) In view of other cases which have come to our notice, however, we fear that the local authority in awarding an allowance of 5d. per mile may have reckoned that that would cover reasonable depreciation by wear and tear; if so, it will perhaps be difficult to persuade another authority—that is, the District Commissioners of Taxes—that that allowance was inadequate.

LETTERS, NOTES, ETC.

Incubation Period of Measles

Dr. J. W. SPRINGTHORPE (late senior physician to the Melbourne Hospital) writes: Those interested in the incubation period of measles (as referred to in the *Journal* of January 3rd and 10th) may be glad to note my experience when in charge of an emigrant ship to Australia in 1884. On leaving Plymouth we had some ninety children on board, many of whom had "colds in the head." Ten days out, a child was found to be developing the characteristic rash. Of course, immediate isolation and fumigation did not prevent a spread. Fourteen days later, however, we had ten cases, apparently from this one source. A fortnight later we had some twenty more, and all the rest of the voyage (eighty-three days) cases everywhere, in all sections of the boat. Thus the natural incubation period of measles would seem to be fourteen days at least. As regards German measles, the incubation period is given in Osler as "usually fourteen to twenty-one days, but varying from one to twenty-eight," and in Anders as "from ten to twenty-one." In an epidemic in which I was able to obtain fairly similar precision I found undoubted cases in which the incubation period seemed to have been not less than twenty-one days.

Amidopyrin in Measles

Dr. T. PIRES (Angers, France) writes: Having followed the correspondence in your columns with regard to the treatment of measles with pyramidon (amidopyrin), I took the opportunity of trying this preparation in a school epidemic. In the three cases where 50 cg. of the crystals were given, the temperatures, ranging between 101.5° and 105° F., were brought down to normal. In two cases the dose was repeated on account of a further rise of the temperature towards the evening, with the same favourable result the next morning. There would seem to be some specific action of the drug in measles, as in cases in which quinine and aspirin were given the temperature remained unaffected. The other symptoms in the whole epidemic called for no comment and seemed unaffected, though the constitutional disturbance was by no means great. This, however, may be because the cases were mild, though in all of them the temperature was considerably raised. An unlucky coincidence in the same school during the measles epidemic was the following case:

A girl complained of malaise, with a temperature of 102.2°. As measles could not be definitely diagnosed she was isolated, and next developed a painful throat. The tonsils were very much enlarged and congested, presenting a deep violet discoloration. Antiseptic gargles were used frequently, and the congested presenting parts began to slough, when Vincent's angina was diagnosed and confirmed by microscopical examination on the fourth day of the illness. The consultant, however, in view of the fact that diphtheria was present in the locality, took a swab the next morning, by which time the whole aspect of the throat had changed, and the uvula was deeply involved in the sloughing process. The swab proved intensely positive for the Klebs-Loeffler bacillus, and antidiphtheritic serum was at once given. There had been no glandular involvement up to this, and the patient is doing well.

The rapid development of the disease in this case may have been due to a sudden decrease in the general resistance of the patient.

Haematocolpos in a Woman of 43

Dr. H. P. DAWSON (Grantham, Lincs) writes: Lately several cases of diseases occurring at unusual ages have been reported in the *British Medical Journal*. Possibly the following may be of interest, both on account of the age of the patient and of the somewhat unusual symptoms. Miss A., aged 43, came up to St. Thomas's Hospital in 1914 at the time when I was house-physician to Dr. Walter Tate. She was suffering from acute retention of urine and much pain. There had been slight difficulty with micturition for about two years. On abdominal examination I found a cystic tumour rising out of the pelvis and extending upwards to one inch above the umbilicus, and at the summit of this, but just to the left side, a small, harder mass could be felt (the uterus). On vaginal examination a bulging membrane was present, pink in colour, except at the centre, where it had a bluish tinge. At operation 3½ pints of dark reddish blood flowed out, together with a few clots. The last part of the fluid was a dirty yellowish-brown, as if mixed with pus. On vaginal examination after operation the cervix could be felt, and admitted a finger-tip. The uterus was slightly enlarged, probably showing a very early haematometra. At no time had there been a period, and the patient also stated that one of her sisters had only a small period about every two years.

Cornu Cutaneum

Dr. T. H. CROZIER (Belfast) writes: Dr. F. H. Unwin's letter in the *Journal* of April 4th (p. 610) interested me very much, as I came across a fine specimen of cornu cutaneum in the wards of the Belfast Infirmary a few weeks ago. The patient was a woman of 60 years, and she first noticed the growth about twenty years ago. There was no history of previous injury. She had a tough, inelastic, keratinous tumour growing from the skin covering the tibial crest. Its over-all length was about 7 inches, and its surface was grooved and pitted like a ram's horn. The base showed signs of partial fracture, and was roughly elliptical in cross-section, with a long axis of about two inches. Unfortunately the patient was very proud of her "horn," and rejected all overtures for its removal. Probably the growth commenced as a wart in this case.

A "Service Week" for Motor Cars

Messrs. Mann Egerton and Co., Ltd., the officially appointed engineers to the Medical Insurance Agency, are arranging a series of "service weeks," from April 27th, when experts will be at the service of medical men, and will, on request, inspect, test, and give assistance or advice in connexion with any make of car, free of charge. The first service week is for Austin cars, and lasts from April 27th to May 2nd inclusive; other well-known makes will follow. Appointments can be made by telephone (Paddington *9011*), or by letter addressed to the manager of Mann Egerton's Service Depot, Church Street, Edgware Road, N.W.8. A further service offered by the firm is the loan of a good saloon, at a nominal charge, while a doctor's car is being repaired.

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 51, 52, 53, 54, 55, 56, 57, 60, and 61 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 58 and 59.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 159.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

388 Myopathia Infraspinata

G. WILTRUP (*Ugeskrift for Laeger*, February 12th, 1931, p. 157) has in the course of several years examined about 600 patients suffering from a condition he calls "myopathia infraspinata." Most of his patients were males between the ages of 30 and 50, who, while at work, felt pain in the shoulder, most frequently the right shoulder. This pain began quite suddenly, was often intense, and sometimes radiated out to the fingers. Rest and bandaging had, as a rule, little effect, and the pain was often worse at night. The pain kept the joint immobilized, often at a higher level than the other shoulder. The upper arm was held to the side, active movements about the joint could not be carried out, and passive movements were at first hindered by the muscular spasm, which yielded somewhat to a few minutes' massage. The range of movement about the joint was then so wide that disease of the joint itself could be eliminated. Normal sensation and reflexes were retained. On palpation, tenderness was demonstrable in the infraspinatus muscle, most frequently in its upper median portion. The pain evoked by this pressure resembled the spontaneous pain of which the patient had complained, and often radiated to the fingers. This condition, which nearly always clears up with massage, is in the author's opinion due to muscular hyperfunction. The diagnosis is easily made, and the examination is best conducted while the patient lies on his abdomen with his hands under his forehead or hanging down by his sides.

389 Estimation of the Pirquet Reaction

J. LEIKVAM (*Norsk Mag. f. Laegevid.*, March, 1931, p. 251) made comparative observations on 2,500 Pirquet reactions at the end of twenty-four, forty-eight, and seventy-two hours, with the following results. A positive reaction showed a marked tendency to remain the same or to increase up to the third day, whereas the non-specific reaction disappeared in the course of the second or third day. Of 160 papules with a diameter of 1 to 5 mm. and more, twenty-four hours after injection of the tuberculin, 122 had already disappeared by the third day. As only about 4 per cent. of the reactions which are negative seventy-two hours after the first Pirquet test become positive after the test has been repeated, Leikvam concludes that these transient reactions, which contribute 72 per cent. of the papules appearing on the first day, are false, non-specific reactions. He considers that Frölich's estimate of 84 per cent. positive Pirquet reactions among school children in the lowest classes should be reduced to 24 per cent., since Frölich probably regarded the non-specific reactions as positive. Late reactions first appearing on the second or third day, or cases which require repetition of the test before they become positive, are frequent at all ages.

390 Control of Diphtheria in Institutions

C. JENSEN (*Deut. med. Woch.*, February 20th, 1931, p. 324) records the results of immunization against diphtheria with Ramon's anatoxin in a large children's home, and in an institution for the mentally deficient, during a period of two years. The results were regarded as favourable, on the following grounds. (1) In the children's home, where all the Schick-positive inmates had been previously immunized, four carriers were allowed to mix freely with the others for a whole month without any case of diphtheria arising. (2) In an isolated department of the home two cases of diphtheria occurred nine months after the immunization had been carried out. The department at that time contained 58 immunized and 6 non-immunized children. The source of infection was found to be two immunized children with suppurative otitis media who had diphtheria bacilli in the discharge. (3) Both of these chronic carriers were allowed to mix freely with the 60 children in another department who had been immunized, but no more cases of diphtheria occurred. As the result of clinical experience and control Schick tests, the author concludes that the duration of immunity is more than two years, and probably considerably more. In children below the age of 7 the injections of anatoxin caused little or no reaction.

391 Measles Meningitis

M. LIORET (*Thèse de Paris*, 1930, No. 484) records 10 cases, two of which are original, in patients aged from 3 to 40, in whom measles was complicated by meningitis. His conclusions are as follows. Apart from local causes, especially otitis, meningitis is a rare complication of measles. It is most likely to occur when the eruption is beginning to fade, and is accompanied by rise of temperature and constitutional disturbance, but without signs of severe involvement of the nervous system. The cerebro-spinal fluid shows a mononuclear reaction; the lymphocytes often predominate, suggesting the presence of tuberculous meningitis, although all the laboratory investigations are negative. This form of measles meningitis disappears rapidly and has no sequels. It resembles the meningitis found in numerous infectious diseases, such as scarlet fever, mumps, and herpes, in its mode of onset, and clinical and laboratory signs. The etiology is uncertain, but it is reasonable to attribute the condition to the measles virus.

Surgery

392 Cholecystectomy without Drainage

G. COTTE and H. ROLAND (*Rev. de Chir.*, January, 1931, p. 1) discuss the advantages of cholecystectomy without drainage in certain cases. It is only advisable when there are no adhesions between the gall-bladder and colon or duodenum, when haemorrhage is slight, and when perivesicular suppuration is not present. In relatively simple cases, and those in which it has been possible to preserve sufficient peritoneal covering to peritonize the bed of the gall-bladder and to bury the stump of the cystic duct, ideal cholecystectomy is the operation of choice. This obviates the employment of any form of drain, the removal of which may be very painful and may break down adhesions, thus causing peritoneal or general infection. A case is mentioned in which secondary haemorrhage of the cystic artery occurred when the gauze drain was removed, and caused the death of the patient. Convalescence after an ideal cholecystectomy is also shortened, and post-operative adhesions and hernia are less likely to occur. Twenty-two cases of cholecystectomy were so treated in the two years under review, and in every case a good and speedy recovery was made. In eleven cases the operation was for gall-stones, in the remaining eleven for pain in the gall-bladder region and chronic cholecystitis with no stone formation. Operation was in most cases carried out under spinal anaesthesia through a Sprengel's transverse incision.

393 Early Signs of Cancer of the Tongue

W. F. MACFEE (*Annals of Surgery*, February, 1931, p. 481) finds that cancer of the tongue is in 20 per cent. of the cases anatomically situated so as to escape early detection. Moreover, it is frequently symptomless, or associated with indirect and consequently misleading symptoms; thus abdominal pain may result from the referring of the pain to other areas of the vagal distribution. One of the first and most consistent symptoms of lingual cancer is, he thinks, pain in or about the ear, when the growth is situated in the posterior half of the tongue. There may also be

some difficulty in swallowing and in dislodging particles of food from the teeth; this is probably due to the replacement of muscle by tumour tissue, and to the involvement of the motor nerves. A queer tickling sensation in the tongue has been reported, probably indicating sensory nerve disturbance. Later symptoms include salivation, pain in the tongue itself, and fetor, but when these appear the condition has usually passed the stage when an operation can be of any use. Other possibly early symptoms noted by MacFee are: deviation of the tongue to the side of the lesion; a slight dimpling, furrowing, flattening, or other evidence of the surface mucous membrane; a defect in speech; a minute ulcer at the most superficial part of an infiltrating cancer; an area of induration; and enlarged lymphatic glands in the neck—a later sign, but even then too often attributed to causes other than lingual cancer. The author adds that as soon as an ulcerated or indurated area is discovered in the tongue a correct diagnosis must be made rapidly, or the condition may become hopeless.

394 Surgical Treatment of Graves's Disease

A. TROELL (*Nord. Med. Tidskrift*, February, 1931, p. 129) traces the marked decline in the operation mortality of Graves's disease in the past decade to careful preparatory treatment modified according to individual needs. The duration of such preparatory treatment must depend on the degree of toxicity in each case; in 9 of his cases it lasted from six weeks to five months. Of 458 thyrotoxicosis patients operated on between 1919 and 1930, 22, or 4.8 per cent., died in connexion with the operation. In the earlier part of this period—from 1919 to 1924—there were 104 patients, 10 of whom (9.6 per cent.) died in connexion with the operation. In the latter part of this period—from 1925 to 1930—there were 354 patients, 12 of whom (only 3.3 per cent.) died in connexion with the operation. The best operative results were obtained in 1929 with a series of 160 cases and only three deaths. As for the late results, the fate of 10 of the 246 patients operated on between 1919 and the end of 1929 could not be ascertained. Complete recovery and fitness for work (with persistent exophthalmos in some cases) was achieved in 51 per cent., and complete fitness for work, without removal of all the symptoms, in 39 per cent. In 3 per cent. the patients were better, but not fully fit for work; in 1 per cent. they were no better or worse; and in 6 per cent. they had relapsed. In view of the danger of hypothyroidism and parathyroid disturbances following extensive bilateral resection, the author has of late been less radical in his operations, preferring to leave a piece of the gland, about as large as a walnut, on each side of the neck.

395 Ankle Fractures with Backward Dislocation

M. LANGE (*Münch. med. Woch.*, February 27th, 1931, p. 365) states that the treatment of fracture of the ankle is made difficult by the fact that the gastrocnemius, pulling at an advantage over its antagonists, tends to increase the backward displacement of the foot and to prevent the maintenance of the correct position after reduction. By flexion of the knee the gastrocnemius is shortened and its power is decreased. Fractures of this nature should be reduced and put into plaster with the patient in the prone position, and the knee and foot both flexed to a right angle. In order to maintain the position the plaster should extend up to the middle of the thigh. This technique has been recommended by several writers on orthopaedics, but is, in the author's opinion, still insufficiently practised.

396 Traumatic Separation of the Symphysis Pubis

J. W. SEVER (*New England Journ. of Med.*, February 19th, 1931, p. 355) cites several cases of traumatic separation of the symphysis pubis; in many of these suturing or wiring of the symphysis was performed. With Wishner and Mayer, and with Timm, the author believes that conservative measures should be generally followed, and that an operation is indicated only in unusual cases where other methods fail. Wishner and Mayer consider that functional cure is possible by gradual lateral compression of the pelvic bones, which restores them to the approximately normal positions. Three cases, in which severe injuries were present without intrapelvic soft part complications, are recorded by Sever; these show that functional recovery may occur despite considerable separation at the symphysis, even if perfect anatomical reposition is not obtained. A heavy swathe, kept tight, is usually sufficient support to the pelvis; this procedure of Wishner and Mayer to ensure constant pressure is thought by Sever to be useful, and could be employed.

Therapeutics

397 Treatment of Malaria

J. A. SINTON (*Indian Journ. of Med. Research*, January, 1931, p. 831) discusses the effects of various quinine dosages and the duration of treatment in malaria. By prolonging treatment the permanent cure rate can be increased, but the increase is not directly proportional to the duration of treatment or to the total amount of quinine given. Moreover, better effects and more permanent cure follow the administration of the larger doses of quinine; the continued use of large doses over long periods may, however, have harmful effects, and may even prolong the disease. The optimum daily dose has been found to be 30 grains. Such a dosage for a short period (one week) should cure at least 70 per cent. of fresh malarial infections, if care is taken that the dose is retained and absorbed. In further papers (ibid., pp. 845 and 855) on the influence on the duration of the disease exerted by special parasite species, and the relationship of season to the cure rate, Sinton considers that there is no certain proof of the existence of variations in the strain or virulence of malarial parasites other than *P. vivax*. It seems highly probable that the relapse rates may be correlated to atmospheric temperature, and especially to the association of a high relative humidity with a high atmospheric temperature.

398 Renal Complications of Bismuth Therapy

L. BORY (*Paris Méd.*, March 7th, 1931, p. 221) says that apart from experimental or accidental intoxications nephritis is not actually caused by bismuth, and prefers to speak of "renal complications during bismuth treatment." The functional renal troubles thus described are polyuria, albuminuria, and sedimentary nephrosis. Polyuria is a natural consequence of bismuth treatment, and has no serious significance; oliguria occasionally follows, however, and must be regarded as a sign of kidney trouble. Albuminuria is the first sign of cell fatigue; epithelial desquamation ensues later, and this calls for interruption of treatment. The author adds the practical hint that in successive periods of treatment the basal drug should be varied; the prolonged employment of bismuth fatigues the kidneys, and a temporary change to a course of arsenic is suggested in order to give them a rest.

399 Treatment of Diphtheria Carriers

R. WAHL (*Deut. med. Woch.*, February 13th, 1931, p. 276) records the results of *x*-ray treatment of a number of diphtheria carriers, many of whom were old and resistant cases. Three positive swabs had been obtained from all the cases before treatment, and, according to the localization of the bacteria, the nose or throat was *x*-rayed, the initial dose being 30 per cent. of a skin erythema dose, followed later by applications of 10 per cent. The tonsil was treated by directing the rays through the skin of the neck, in the region of the angle of the jaw. In all, 136 cases were treated (1 streptococcal, 2 meningococcal, and the rest diphtheria); 105 were negative after the first treatment, 28 after the second, and 2 after the third. Thus all patients except one were cured by three applications or less. The interval between the applications was about a week, swabs being taken about five or six days after each, since it was found that swabs taken directly

after treatment are still positive. This fact, and the observation of others that cultures of diphtheria bacilli cannot be sterilized by the direct application of *x* rays, suggests that the results of treatment are due to an effect on the tissues, and not on the organisms themselves.

400 Local Treatment of Leprosy with Chaulmoogra Oil

T. J. DIMITRY (*Amer. Journ. Trop. Med.*, January, 1931, p. 65) has been successfully treating the eyes and nasal cavities in leprosy with instillations of chaulmoogra oil, either pure or diluted with olive oil. The greatest improvement followed the use of the oil, either pure or diluted, by means of atomization into the nasal cavities. The author is now trying the pure ethyl ester "chaulmestrol," and finds it less painful than the pure oil, though its administration is followed by a burning sensation—never very great—which lasts about half an hour. Dimitry emphasizes the importance of carefully investigating the nasal passages and sinuses in leprosy on the ground that these cavities harbour the cause of the repeated attacks of inflammation in the eyes, and of the persistent nature of the disease generally in the body. Atomization of chaulmoogra oil or of its derivatives can well be combined with the oral or hypodermic method of administration now in general use.

Dermatology

401 Parakeratoses of the Ends of the Fingers

R. SABOURAUD (*Ann. de Derm. et de Syph.*, February, 1931, p. 206) describes a parakeratosis of the ends of the fingers; of slow and recurring evolution, it is streptococcal in origin, and supervenes after a whitlow. This lesion, formerly confused with the eczemas, is often mistaken for a mycosis, which it much resembles. The two conditions may be differentiated by the following points. A parakeratosis has an antecedent history of whitlow, and is much more frequent on the fingers than on the toes. The centre of it is the end of the finger and edge of the nail, and it usually starts in the groove under the free border of the nail. Mycoses, common on the toes, may be recognized by a subungual yellow streak which, commencing at the free border of the nail, runs vertically towards the matrix. Parakeratoses may become secondarily infected with staphylococci, and hence give mixed cultural growths. The primary treatment of both conditions is a daily brisk friction with 1 per cent. iodized alcohol; an ointment should then be applied. Mycoses yield readily to a benzoic, salicylic, or chrysophanic acid ointment. Parakeratoses heal much better with an ointment of 1 in 30 to 1 in 10 (or even stronger) coal tar. To facilitate removal of the black discoloration caused by the latter, the fingers should be cleansed with a greasy substance before soap and water is used.

402 Cutaneous Calcinosis

E. R. MALONEY and D. BLOOM (*Arch. Derm. and Syph.*, February, 1931, p. 245) report a case of cutaneous calcinosis, a disease characterized by the presence of calcareous tumours and plaques in the skin and subcutaneous tissue. Local and general forms exist, the first including calcification in tumours, and being a purely local disease not dependent on any general disturbances. The second form, known as metastatic calcinosis, may be due to the presence in the blood of excessive amounts of calcium, resulting from bone destruction through osteomyelitis, caries, or lymphatic leukaemia. The cutaneous tumours or plaques vary in size and consistency; they eventually perforate the skin, and discharge a creamy mass containing calcium phosphate with some calcium carbonate. In most cases the blood contains only the normal amount of calcium, but in the metastatic cases an excess is usual. The authors' patient was a boy, aged 14, in whom there was a history of preceding throat infection, severe nephritis, and signs of endocrine disturbance. Multiple tumours were present in the skin and subcutaneous tissue of the hands, elbows, knees, right buttock, and behind the right ear. The patient had a prominent jaw and nose, a senile facial expression, a funnel-shaped chest, the female type of pubic hair growth, small testes, thin arm muscles, and a large lipoma beneath the left scapula. His intelligence was normal. *X*-ray examination of the chest revealed hilar shadows in both lungs, with a number of calcified glands and areas of infiltration in the lower lobes. This case belonged to the group of metabolic general calcinosis, and the authors think that the preceding nephritis with confinement to bed for many weeks may have so disturbed the physicochemical balance and solubility of the calcium in the blood as to have produced the condition.

403 An Endocrine Factor in Acne

B. BLOCH (*Brit. Journ. of Derm. and Syph.*, February, 1931, p. 61) holds the view that acne in its first phase is a consequence of the physiological functioning of the sexual glands, analogous to that which is generally assumed for the development of the normal secondary sexual features, such as the formation of terminal hair. Acne, and particularly its basis the comedo, appears at a determined age, and is so widespread as to be regarded inevitably as a hormonal disease of the organism at the time of puberty. Statistical evidence is given in support of these views, based on the examination of 4,191 children in Zurich. Acne was found to attain its maximum incidence at the age of 17 in girls and at 18 in boys, the gravest cases beginning at about the age of 10 or 11, and being more serious in boys than in girls. Other supplementary evidence of a similar purport is cited.

404 Gold Pigmentation of the Skin

L. NOVÉ-JOSSERAND, GATÉ, CHARPY, JOSSERAND, and P. CUILLERET (*Bull. Soc. Française de Derm. et de Syph.*, January, 1931, p. 117) report the cases of three children suffering from pulmonary tuberculosis, treated continuously for two years or more with intravenous doses of gold salts. In each case the skin of the face after about eighteen months began to show a violet-blue pigmentation recalling the tint seen in argyrosis or in mild aniline poisoning. Only those parts of the skin constantly exposed to the light were affected—namely, the face and neck in a girl, and in two young boys parts of the legs as well; otherwise there were no signs of intolerance or intoxication. The authors recall the great rarity of this condition, and suggest for it the name "chrysocyanose" as being more descriptive and more etymologically exact than "chryose," the term given to it by Zimmerli and Lutz in a comparable case.

Obstetrics and Gynaecology

405 Endometrial Haemorrhage

Believing that the accepted methods of treatment of irregular uterine haemorrhage are empirical and somewhat limited, M. G. SUTTON (*Med. Journ. of Australia*, January 10th, 1931, p. 34) has endeavoured to correlate the clinical histories of patients suffering from this condition with the pathological findings. A short review of the function of menstruation and of its comparative and intrinsic physiology is given, together with the histology of the cyclic changes in the ovary and endometrium. Certain pathological entities of the uterus and endometrium which have been considered to underlie uterine haemorrhages are discussed; such are subinvolution, metritis and endometritis, glandular hyperplasia, and menstrual irregularities. The treatment of these conditions is briefly outlined. Sutton states that, except in bleeding due to retained products, fibroid polypi, and cancer of the uterine body, irregular uterine haemorrhage is extrauterine in origin and often extrapelvic; to the latter class belong the metropathies. Chronic metritis is an infrequent condition, associated with chronic interstitial endometritis, the late result of which is true fibrosis uteri. Paraclimacteric fibrosis is only a relative condition,

and not inflammatory in origin. So-called chronic subinvolution is a misconception; it should be termed "the parous uterus." None of these conditions usually causes uterine bleeding, though they may aggravate and prolong it. Before the menopause the uterus should be conservatively treated, not only because of its gestational function, but also because, due to its complex structure, it possesses an endocrine function and one relating to calcium economy. When haemorrhage is not due to malignancy or large fibroids, partial hysterectomy or myomectomy with ovarian conservation, and *x*-radiation of the thyroid gland, pituitary body, and spleen should be considered. If these fail it may be necessary to procure the destruction of the endometrium by radium or surgical diathermy.

406 Eclampsia

A. C. BECK (*New York State Journ. Med.*, March 1st, 1931, p. 274) reviews the sequels of eclamptic attacks in a series of 97 consecutive cases during the past sixteen years. In the first four years of that period the treatment adopted was the prompt removal of the products of conception, followed by drastic eliminative measures designed to combat the toxaemia; the mortality was 25 per cent. During the next four years neither interruption of pregnancy nor hastening of labour was attempted unless there was some indication other than eclampsia, morphine in large doses and mild eliminative measures being relied upon; the results were much better. In the last eight years of the period it was clearly recognized that eclamptic patients were so hypersensitive to external stimuli that convulsions might be provoked by very slight irritation, such as the passage of a stomach tube, the insertion of a rectal tube, catheter, or hypodermic needle, or by blood pressure determinations. By avoiding all external stimuli as far as possible, placing the patient in a darkened room, and the routine early withdrawal of blood up to 1,000 c.cm. (unless contraindicated by fall in blood pressure or rapid rise in pulse rate), and by the administration of ½-grain doses of morphine hourly until the convulsions ceased or the respirations fell below 12, the mortality was reduced to 6.3 per cent. Beck adds that since no further convulsions occurred after early phlebotomy in 30 out of 40 cases, it seems probable that the lower mortality was largely due to this procedure. The foetal deaths were high throughout the period under review.

407 Labour in the Elderly Primipara

J. P. MAXWELL and A. I. H. WONG (*China Med. Journ.*, February, 1931, p. 113) believe that there is no class of case in which the obstetrician needs to exercise so much thought and care in planning labour as in primiparae over the age of 35. They record a series of 46 such patients seen in the course of nine years in a consecutive total of 2,226 labour cases at the Peking Union Medical College Hospital, and report that the length of labour was far greater than the time taken in the average primipara. There were an abnormal number of occipito-posterior presentations—roughly, one in three of the head presentations—and the numbers of episiotomies and perineal repairs were much above the normal figure. Whereas the Caesarean section rate for the total of these patients was 4.9 per cent., in the elderly primiparae it was as high as 17.3 per cent. Premature rupture of the membranes was frequent; in 13 out of the 46 cases this had occurred, and in most cases long before birth. Three Caesarean sections were performed owing to failure of the cervix to dilate, and on each occasion great difficulty was experienced in detaching the membranes. No forceps delivery was attempted on [illegible] in which the cervix was not fully dilated, and the [illegible] labour in these cases indicated primary uterine [illegible] one cause of the difficulties encountered. From [illegible]s nine living children were obtained after the [illegible]s had been known to have been ruptured for a [illegible] before birth, similarly indicating primary inertia. [illegible]here is the likelihood of no further children being [illegible] consequent[illegible]s h[illegible] greater need for special care [illegible] that th[illegible]s fail. W[illegible] be born alive and healthy.

Pathology

408 Excretion of Water and Salts from the Kidney

I. SCIMONE (*Biochim. e Terap. Speriment.*, December 31st, 1930, p. 469) has studied the elimination of water and salts from the kidney after intravenous injections of isotonic solutions of sodium chloride. A series of eighteen rabbits received into the right jugular vein, at the rate of 3 c.cm. per minute, amounts of isotonic salt solution (9.74 grams per litre) ranging from 200 to 600 c.cm. per kilo of body weight. The bladder was ligatured above the urethral orifice, and a glass cannula introduced near the upper end was connected by rubber tubing to a graduated cylinder in which the urine secreted was collected. Measurements were taken of the urine secreted during the injection, and again after three hours' interval. The total excretion increased proportionally to the amount of saline solution injected; the quantity excreted during the injection was several times greater when large amounts were injected than when only small amounts were injected. The total percentage volume of water and the total percentage amount of chloride secreted showed a parallel relation, both increasing as the amount of solution injected was increased, a result to be expected from the necessity of maintaining a constant osmotic pressure of the blood and tissues.

409 Etiology of Gastric Ulcer

Gastric ulcer occurs chiefly along the lesser curvature and in the pyloric region of the stomach, where the mucous membrane secretes no acid but is exposed to the acid secretion formed by the body and greater curvature. It may therefore be due to an excessively concentrated acid secretion, or to a failure of the mechanism which protects the cells. The parts of the stomach actually concerned in the secretion of acid are presumed to be better able to withstand its action. In order to demonstrate the truth of this theory P. SIEBERT (*Deut. med. Woch.*, March 6th, 1931, p. 399) has performed a series of carefully controlled experiments on rats, and has consistently produced multiple gastric erosions by injecting histamine while the animals were fasting, thus producing a powerful and undiluted secretion of acid. The number of ulcers produced corresponded roughly with the number of histamine injections, and some animals developed erosions by starvation alone. The ulceration invariably occurred in that portion of the rat's stomach which does not secrete the acid juice but is exposed to its action.

410 Insulinaemia in the Fat and Thin

D. COLUMBA (*Il Policlinico*, Sez. Prat., February 16th, 1931, p. 219) investigated the amount of insulin in the blood of 12 constitutionally fat and 10 thin persons by the method of Dodds. He found that in every case the hypoglycaemic power of the blood was lower in fat than in thin persons. He therefore came to the conclusion that fat persons present a condition of hypo-insulinaemia which may be regarded as the expression of a latent state of functional insufficiency of the pancreas.

411 Latent and Occult Tuberculous Infection of Bronchial Glands

W. M. CUMMING, S. J. HARTFALL, and J. G. THOMSON (*Journ. Path. and Bact.*, March, 1931, p. 157) examined histologically and by guinea-pig inoculation the tracheobronchial glands of 108 cadavers for the presence of tubercle bacilli. These organisms were found in seven cases, of which four showed no histological evidence of tuberculous lesions. All the seven strains isolated were of the human type, indicating that infection had probably occurred by the respiratory route. Since in the selection of suitable cadavers all cases showing evidence of active tuberculosis were excluded, it follows that these seven cases were all examples of latent tuberculosis, though there is no definite proof that the bacilli were not actively multiplying in the glands.

What about taste?

MANY patients still believe innocently that the medicine must be bitter to be efficacious.

Agarol Brand Compound the original mineral oil and agar-agar emulsion with phenolphthalein, is for that up to date generation that wants its medicines in the proverbial "sugar coating."

No excuses are needed for its taste any more than for its effectiveness. Agarol Brand Compound is exceptionally palatable without artificial flavouring. It *flows freely* from the bottle, and can be mixed with any liquid or soft food.

Just enough mineral oil to carry unabsorbable moisture to the intestinal contents, keep them soft, and so make evacuation easy and painless. By *gentle stimulation* of peristalsis, Agarol Brand Compound makes the result certain, and aids in re-establishing regular habits.

One tablespoonful at bedtime —is the adult dose

Final decision on the true worth of Agarol Brand Compound rests with the physician. We will gladly send a liberal quantity with literature, for trial.

AGAROL BRAND COMPOUND *for Constipation*

Descriptive booklet sent free on application

A MAYTON writes:

"The Table which you supplied for my Nursing Home is giving great satisfaction, and the Surgeons who work here find it convenient for all operations. It is just as convenient for ear, nose, and throat, as for gynaecological ones. The advantage of your Table over others we have had is the rapidity with which the position of the patient can be changed without any strenuous work on the part of the Nursing Staff."

A LONDON SURGEON writes:

"Your Operating Table I already know well as we have one at the —— Hospital. It is *far and away* the best, simple, cheap operating table that I have met, and I should like to recommend it very highly."

FOR DEAFNESS

Doctors prefer "ARDENTE" because—

"ARDENTE" STETHOSCOPE.

Mr. R. H. Dent makes a Stethoscope especially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, as evidenced by the interest shown at the last B.M.A. Meeting.

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises, giving inconspicuous hearing.
4. It conveys sounds from varying ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf through various causes.
7. It is helpful for conversation, music, talkies, wireless, home, office, public work, and sports.

FREE HOME TESTS

arranged for Doctors and Patients.

Medical Prescriptions made up to the minutest detail.

MEDICAL REPORTS.

Commended by all leading medical journals.—Mr. Dent will be happy to send full particulars and reprints on request.

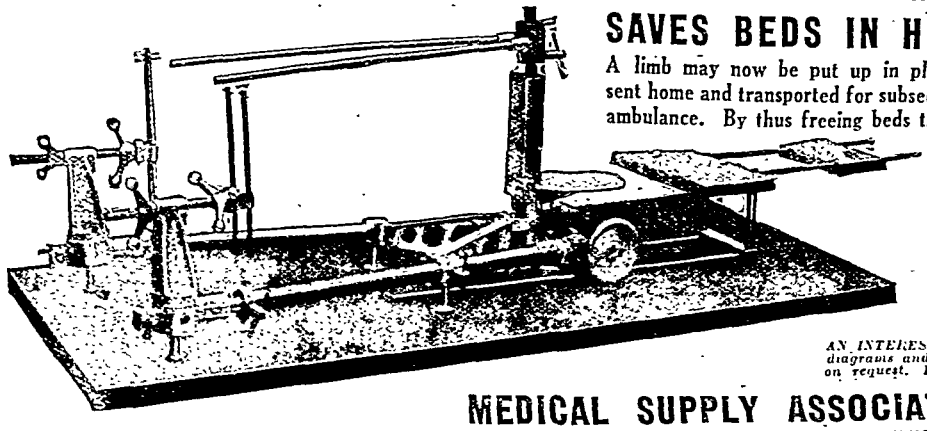
An IMPROVED and MODIFIED

Portable Traction Apparatus

An exceedingly efficient and convenient apparatus for putting up in plaster the lower limbs or trunk; also when applying bone plates or Parham and Martin's Bands to long bones of the lower extremity. Provides the more essential movements of expensive and bulky Orthopaedic tables at a fraction of the cost.

Quickly adaptable for the following positions:

Extension of whole lower limbs.
Movements about hip-joint:
Abduction to any degree—
Hyperextension—Flexion—
Internal and External Rotation.
Flexion of knee-joint.
Inversion and Eversion of foot.



SAVES BEDS IN HOSPITALS

A limb may now be put up in plaster, the patient sent home and transported for subsequent treatment by ambulance. By thus freeing beds this new apparatus saves its cost many times over.

Folds compactly for storage or transit in plywood case 35 in. × 15 in. × 11 in.

AN INTERESTING LEAFLET giving diagrams and instructions, post free on request. Please ask for a copy.

FOR INTERNAL TREATMENT OF
GONORRHOEA, URETHRITIS AND OTHER AFFECTIONS
OF THE GENITO-URINARY TRACT
SANTAL MIDY CAPSULES have been prescribed with uniform success for over thirty years.
Distilled from carefully selected Mysore Sandal-Wood, the oil is bland and remarkably
FREE FROM THE IRRITANT AND NAUSEATING EFFECTS
which are provoked by many preparations.
There is marked absence of gastric and other disturbances, diarrhœa and skin eruptions. Its mild chemotactic properties permits its administration in relatively large doses without fear of too violent reaction or intolerance.
SANTAL MIDY CAPSULES may be prescribed and relied upon in all stages of Gonorrhœa and in other forms of Urethritis and affections of the Genito Urinary tract.
The Capsules contain 5 drops, and usually 10 to 12 are given daily in divided doses.
Prepared in the Laboratoire de Pharmacologie Generale, 8, Rue Lavoisier, Paris, and sold by most Chemists and Wholesale Druggists throughout the World
U.K. Agents: WILCOX, JOZEAU & Co., 75, Gt. St. Andrew St., W.C.2.

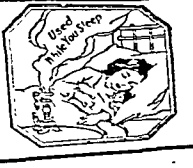
WHOOPING COUGH

The best practice in the treatment of whooping cough recognizes the importance of keeping the patient out of doors as much as possible. The food should be easily digestible, nourishing, and given a little at frequent intervals.

There are no specifics for this disease. In very young children drugs are administered with difficulty and are of uncertain effect.

Vaporized Cresolene at night will be found a simple and effective means of preventing the paroxysms at that time, thus tending to preserve the strength of the patient, avoid complications, and hasten convalescence.



ALLIANCE DRUG & CHEMICAL CO.

Safeguarding the Purchaser.

Although Advertising has become an integral part of modern business, its advantages to the consumer are not always clearly realised. A little thought will show, however, that any product marketed under a recognised name or trade mark must reach a high standard of quality, for were this not so "repeat sales" could not be secured; recognition of a discredited brand reacting to the disadvantage of the manufacturer in inverse proportion to the benefits that are derived when a large and satisfied clientele see, in the name of the product, a guarantee of quality and efficiency.

This argument leads one to expect that branded goods will represent better value than others, and that the standard will be maintained.

Advertising further benefits the purchaser by making possible reductions in the selling price consequent upon increased production resulting from the larger demand created by the advertising campaign. The manufacturer of advertised goods places his cards upon the table, supplying information concerning the product which enables the prospective purchaser to form a judgment upon its suitability to his own particular needs, whereas non-advertised goods rely entirely upon recommendations, often of a confused nature, and it is left to the purchaser to find at his own cost the real value of the product.

It is safe, therefore, to assume that in the majority of cases advertised goods only should be purchased. The advertisement pages of the *Journal* contain offers of a variety of goods and of service designed to meet the professional and personal needs of the medical man.

It should be remembered that while the acceptance of advertisements for publication in the *Journal* is not to be understood to imply a recommendation or guarantee, and while no responsibility can be accepted with regard to the accuracy of the statements contained in advertisements, a very strict censorship is maintained by the Journal Committee, and every effort is made to ensure that the claims set forth are well founded. In this way a degree of confidence has been established between readers and advertisers in the *British Medical Journal* which cannot be paralleled by any other similar publication in the British Empire.

The Collection of Overdue Accounts

To cure bad payers, i.e., to turn bad payers into good ones, is always a difficult problem. We not only succeed in carrying out this difficult task, but, in addition, we improve the relationship between Patient and Practitioner.

All Medical Institutions and Nursing Homes are included in our scope.

Your visiting card marked "B" placed in an envelope will produce all information.

REGISTERED NURSING HOME for PERMANENT PATIENTS.
3, Broadhurst Gdns., London, N.W.6.

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS,

NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

President: LORD WAKEFIELD OF HYTHE, C.B.E., LL.D.
Treasurer: SIR LIONEL FAUDEL-PHILLIPS, Bart.
Physician-Supt.: J. G. PORTER-PHILLIPS, M.D., F.R.C.P.

This Registered Hospital is now situated at Monks Orchard, in some 250 acres of park, pleasure, and farm grounds.
Applications can be considered on behalf of patients of the educated classes in a presumably curable condition.
With a view to early treatment voluntary or uncertified patients are admitted.
Patients who can contribute 5 guineas weekly towards the cost of treatment and maintenance may be received as vacancies arise. The Committee will also consider applications for admission at lower rates, and in certain cases will be prepared to admit patients free of charge.
Every facility for specialized investigation and treatment is provided in the *Lord Wakefield Science and Treatment Unit*. In this Unit is found the X-ray and Dental Departments and the Bio-Chemical, Pathological, and Psychological Laboratories.
Furthermore, provision is made for Electro-Therapy and Hydro-Therapy to be carried out in all their forms.
In addition to the Resident Medical Staff, Consultants in special branches of Medicine and Surgery are available whenever required.
The comfort of sensitive patients is greatly enhanced by the fact that the majority are given single bedrooms.
For forms and further particulars apply to the Physician-Superintendent at the Hospital

City and County of Newcastle-upon-Tyne.

EDUCATION COMMITTEE.

Applications are invited for an appointment as Full-time ASSISTANT SCHOOL MEDICAL OFFICER (man or woman). Salary £500 per annum, rising by £25 per annum to a maximum of £700 per annum, in accordance with the National Scale. Applicants should have had at least three years' experience in the practice of their profession subsequent to obtaining their qualifications.

Special experience in the administration of Anaesthetics is essential.

Form of application and particulars of the appointment may be obtained by sending a stamped addressed foolscap envelope to the Director of Education, Education Office, Northumberland Road, Newcastle-upon-Tyne.

Applications will be received up to and including May 9th.

County Council of Middlesex.

DISTRICT MEDICAL OFFICER AND PUBLIC VACCINATOR.

The County Council invites applications from duly qualified Medical Practitioners for the *undermentioned* appointments:

DISTRICT MEDICAL OFFICER, PARISH OF HAREFIELD.

Salary £45 per annum. The officer appointed will be required to carry out his duties in accordance with the Public Assistance Order, 1930, of the Minister of Health, to reside in the district, and to name to the Council some *duly qualified* Medical Practitioner who will, in the case of his absence or other hindrance to his personal attendance, act in his place.

PUBLIC VACCINATOR, PARISH OF HAREFIELD.

The person appointed will be required to produce to the Council a certificate of proficiency in vaccination, unless such certificate was *required* as a condition of obtaining any diploma, licence, or degree which he possesses.

He will be required also to enter into a contract with the Council in accordance with the Vaccination Order, 1930, of the Minister of Health. The contract will provide for the payment of the minimum fees laid down in the Order.

Applications, stating (1) name, (2) age, (3) qualifications and experience, accompanied by copies of not more than three recent testimonials, must be received by the undersigned not later than May 9th.

No special application *forms* are provided. Envelopes must be endorsed "District Medical Officer" or "Public Vaccinator" as the case may be.

Canvassing, directly or indirectly, will be a disqualification.

Guildhall, Westminster, S.W.1. ERNEST S. W. HART, Clerk of the County Council.
April 14th, 1931.

City of Birmingham.

DUDLEY ROAD HOSPITAL.

JUNIOR ASSISTANT MEDICAL OFFICERS (Male).

Applications are invited from fully qualified Medical Practitioners for appointments as Junior Assistant Medical Officers (male) at the Dudley Road Hospital, Birmingham.

The Hospital accommodation is fixed at 926 beds, divided into Medical, Surgical, Children's Infectious, [illegible] Gynæcology and Obstetric [illegible] completely equipped P[illegible] Laboratories, Deep [illegible] Massage, Sunlight and Dental Departments. Approximately 5,000 operations are performed annually.

The appointments will be for a period of six months in the first instance, but may be extended at the end of that time for a further period not exceeding six months.

The persons appointed will be required to assist at operations, to administer anæsthetics, and undertake casualty work and such other duties as may be assigned to them by the Medical Superintendent.

The salaries attached to the appointments will be at the rate of £200 per annum, together with full residential emoluments (rations, apartments, laundry, and attendance).

The officers appointed will be required to pay to the Council all fees, allowances, and emoluments (other than the foregoing) received by them.

Further particulars of the appointments may be obtained from the Medical Superintendent, F. W. ELLIS, Esq., M.D., F.R.C.S., Dudley Road Hospital, Birmingham, to whom applications, stating age, experience, and qualifications, accompanied by copies of recent testimonials, should be forwarded not later than Thursday, May 7th.

F. W. ELLIS, Esq.

Dudley Road Hospital, Birmingham.

Dumfries and Galloway Joint Sanatorium Board.

ASSISTANT MEDICAL SUPERINTENDENT.

Applications are invited for the appointment of Assistant Medical Superintendent of (1) the Board's Sanatorium at Lochnaben, Dumfriesshire, and (2) an *adjoining* Infectious Diseases Hospital. The officer will be required to devote his whole time to the duties and not to engage in private practice. Salary £300, rising by annual increments of £25 to £400 per annum, with board, lodging, and laundry. Candidates must be regularly qualified in Medicine and Surgery.

Full particulars and forms of application may be obtained from the undersigned, with whom applications (on the prescribed form) must be lodged prior to noon of Monday, May 4th.

County Buildings, Dumfries. JOHN ROBSON, Clerk of the Board.
April 18th, 1931.

City of Liverpool.

APPOINTMENT OF MEDICAL OFFICER OF HEALTH.

The Corporation *invite applications* for the position of Medical Officer of Health for the City and Port of Liverpool and Medical Officer to the Education Authority at a salary of £1,600 per annum. The duties will be those *prescribed* by statute, subject to such variations in administration as the City Council may from time to time direct, and will include the general supervision of the Municipal Hospitals.

The officer appointed will be required to devote his whole time to the duties of the office, and will not be allowed to engage in private practice, and all emoluments out of public moneys which may be payable to or received by him will have to be paid to the Corporation.

The officer appointed will hold office subject to the Standing Orders of the Council, and the appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922. He will also be required to reside within the City.

Canvassing of members of the Council will be regarded as a disqualification.

Particulars of duties may be obtained on application to the Town Clerk.

Applications, stating age and qualifications, with copies of testimonials (not exceeding three) endorsed "Medical Officer of Health," addressed to the Chairman of the Health Committee, under cover to the Town Clerk, Municipal Buildings, Liverpool, must be delivered at the Town Clerk's Office, Liverpool, *not later than* May 2nd.

Town Clerk's Office, Liverpool. April 10th, 1931. WALTER MOON, Town Clerk.

County Borough of Burton-upon-Trent.

DEPUTY MEDICAL OFFICER (Male).

The Council invite applications from candidates for the appointment of Deputy Medical Officer of Health, Assistant School Medical Officer, and Assistant Tuberculosis Officer.

Salary £600 per annum, rising to £700 by annual increments of £25, such salary to be inclusive of all duties. The candidate selected for the appointment will be required to pass a medical examination, and the appointment will be terminable by three calendar months' notice on either side.

The person appointed must have a Diploma in Public Health, and must have had not less than three years' post-graduate experience, and will be required to devote the whole of his time to the duties of the office, and to act under the direction of the Medical Officer of Health.

Applications, stating age, experience, and qualifications, and endorsed "Deputy Medical Officer," to be delivered to me, with copies of not more than three recent testimonials, not later than Tuesday, April 28th.

A list of the duties can be obtained on application.

Canvassing any member of the Council will disqualify.

Town Hall, Burton-upon-Trent. April 8th, 1931. H. BAILEY CHAPMAN, Town Clerk.

County Borough of Walsall.

MANOR HOSPITAL. (270 Beds.)

ASSISTANT MEDICAL OFFICER.

Applications are invited from duly qualified gentlemen for the appointment of *Junior Resident* Assistant Medical Officer. The appointment will be for a period of twelve months, and the salary at the rate of £150 per annum, together with the usual residential emoluments.

The person appointed will be required to act under the *general* direction of the Medical Officer, from whom particulars of the appointment may be obtained.

Applications, stating age, professional qualifications and experience, accompanied by not more than three copies of recent testimonials, should be sent to the undersigned at once.

29, Lichfield St., Walsall. April 24th, 1931. C. S. FOTHERGILL, Public Assistance Officer.

Kidderminster Amalgamated

FRIENDLY SOCIETIES AND GENERAL MEDICAL AID ASSOCIATION.

The Committee are prepared to receive applications for the post of MEDICAL OFFICER of the above Institution. Salary £700 per annum, free of fees, car, and allowances.

Applications, with testimonials, should reach the Secretary not later than May 4th.

State age (married or single).

15a, Oxford Road, Kidderminster, Worcs. C. LINCOLN PORTER, J.P., Secretary.

Borough of Hove.

URBAN DISTRICT OF PORTSLADE-BY-SEA.

MEDICAL OFFICER OF HEALTH.

The Council of the Borough of Hove and the Council of the Urban District of Portslade-by-Sea jointly invite applications from qualified Medical Practitioners for the dual appointment of whole-time Medical Officer of Health, etc., for the Borough and the Urban District.

The successful candidate will also be appointed by the East Sussex County Council as Assistant County Tuberculosis Officer for the County District, comprising the Borough and Urban District. Candidates must hold the qualifications prescribed by the Sanitary Officers Order, 1926, and previous experience in Medical Officer's work and Tuberculosis is essential.

The total salary for the combined posts will be £1,000 *per annum*, allocated between the various services as set out in the Conditions of Appointment, copy of which, with form of application, may be obtained from the Town Clerk, Town Hall, Hove. An allowance of £50 per annum will also be made towards the expenses of a motor car, and a holiday deputy will be provided.

Applications, accompanied by not more than three testimonials, should be sent on or before May 4th next to the Town Clerk, Hove.

In respect of the *Borough and the County* there are Superannuation Schemes in force in which the successful candidate will participate subject to the conditions.

W. JERMYN HARRISON, *Town Clerk.*

Town Hall, Hove. April, 1931. ERNEST H. KEMPE, Clerk to the Council.

REGULARITY AND COMPLETENESS OF BOWEL EVACUATION

HOW TO ENSURE BOTH

Attention has recently been drawn to the incompleteness of evacuation common even among those who complacently boast of their regularity.

Completeness, as a distinguished physician said the other day, is "even more important than regularity" in the exercise of this physiological function. Incomplete evacuation doubtless explains why so many people, with regular once-a-day habits, continue to suffer from headache, lassitude, nausea, and all those other symptoms customarily attributed to alimentary toxaemia. The truth is that, in these individuals, the rectal neuro-muscular tension scarcely ever recovers normality.

These discomforts and disabilities can generally be made rapidly to disappear by a minimum effective dose of Eno's "Fruit Salt" taken each morning before the early cup of tea. Eno is a carefully prepared saline laxative of fine granular consistency, instantly soluble in water with effervescence. It is entirely free from the nauseous and irritating mineral salts. Its pleasant taste and refreshing character are due to its chemical purity and physical texture. Another of its advantages is that it contains no sugar or artificial flavouring agent.

"Urgent Abdominal Diagnostics"

The Proprietors of ENO'S "Fruit Salt" will deem it a privilege to send to any member of the Medical Profession a copy of the latest of their series of "Medical Reminders"—with or without a bottle of their preparation as desired. "Urgent Abdominal Diagnostics" summarises the salient facts which need to be ever at the front of the mind when faced with an abdominal emergency. The diseased conditions dealt with include those which most often call for immediate surgical attention. It is bound in black morocco limp to conform to the style of the previous publications in this series.

VENTRICULIN

(Stomach - Tissue Extract, P., D. & Co.)

IN addition to being a specific for the treatment of pernicious anaemia, Ventriculin has a wide application in secondary anaemia. It has been employed with success in the anaemias associated with pregnancy and the puerperium, syphilis, hyperthyroidism, and tapeworm infestation. Ventriculin is also helpful in combating the anaemia which is such a marked feature in sprue, as well as in pulmonary tuberculosis.

Ventriculin is not only the *first* stomach extract shown to have a haematopoietic effect, but each batch is guaranteed to be clinically tested before issue.

Ventriculin is supplied in packages of 12 vials, each containing 10 gms. Further particulars will be sent on request.

PARKE, DAVIS & CO., 50 BEAK STREET, LONDON, W.1.

ISSUED WEEKLY] [COPYRIGHT] [REGISTERED AS A NEWSPAPER

TRADE MARK BRAND

NEOTROPIN

BUTYLOXY-DIAMINO-AZO-PYRIDIN.

A urinary antiseptic of remarkable powers of penetration and tissue affinity; highly bactericidal

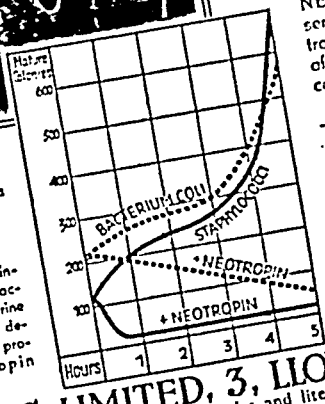
NEOTROPIN is a dye-stuff of the azo-pyridine series and possesses the marked powers of penetration and tissue affinity inherent to dyes. Shortly after its administration it imparts a yellowish red colour to the urine and later the prostatic, testicular and cervical secretions.

The bactericidal effects of Neotropin have been confirmed by a long series of experiments both in vitro and in vivo. Even in a dilution of 1/512,000 it still inhibits bacterial growth.

Its combined penetrative and antiseptic properties render it invaluable in the treatment of Bacteriuria, Cystitis, Pyelitis and Pyelonephritis.

Its freedom from any irritant effect explains its remarkable efficacy in acute gonorrhoea and cystitis.

Original Packing:
Bottles of 30 dragées of 1.5 grains.



The curves show the increase in growth of bacteria in ordinary urine compared with the decrease in growth produced by Neotropin

SCHERING LIMITED, 3, LLOYD'S AVENUE LONDON, EC.3

From whom samples and literature will be sent on request.

What shall I prescribe?

WHEN CONFRONTED WITH A DIFFICULT CASE OF OSTEO OR RHEUMATOID-ARTHRITIS IT IS INDEED COMFORTING TO KNOW THAT QUICK AND LASTING RELIEF CAN BE OBTAINED FROM THE ADMINISTRATION OF

ELIX. FORMASAL AND TAB. ARTHRITONE.

THE POPULARITY OF THESE PREPARATIONS IN RHEUMATIC CONDITIONS IS DUE SOLELY TO THE GOOD RESULTS OBTAINED.

PRACTITIONERS HAVE TAKEN THE TROUBLE TO WRITE AND TELL US OF THE WONDERFUL EFFECTS THAT THESE PREPARATIONS HAVE IN CASES WHERE ALL OTHER FORMS OF MEDICATION HAVE BEEN OF NO AVAIL.

Contains all the valuable constituents

OF FRESH GRAPES

in a specially rich form.

JUVIGOR

Henri de Bahèzre
Proprietaire

Maison fondée
en 1808

Made in Nuits-Saint-Georges, in the heart of Burgundy, famous for its wonderful grapes.

Simple but convincing reasons why Juvigor can be recommended to patients.

A glass of Juvigor contains the vital elements of a large bunch of grapes.

Juvigor is absolutely free from preservative, colouring matter, flavouring, or chemicals of any kind.

In making Juvigor only fresh ripe Burgundy grapes are used. These are lightly crushed in order that only the free juice immediately under the skins is extracted. Only this free juice is used because it contains a very much higher percentage of the most valuable constituents of grape juice; it requires between 11 and 12 pounds of grapes to make one large bottle of Juvigor.

The grape juice is pasteurised without destruction of the vitamins and retains in full all its tonic and nourishing elements.

Juvigor is recommended when the vitality is low, in chronic and debilitating diseases such as tuberculosis, after acute diseases like pneumonia and influenza, especially where there is loss of appetite or the stomach is sensitive. In fact, wherever an increase of vitality is desired.

Note:—Generally speaking it is advisable for patients at first to take Juvigor with an equal quantity of water, or soda water, gradually decreasing the amount of water added.

Sold at 3/- and 1/9 per bottle.

Comfortable, and Correct Support

Assured to all sufferers from abdominal ptosis who wear the Curtis Abdominal Support, Model No. 1. The principle of this support—that of anterior posterior support—has been proved by scientific research to be the most efficient. There is no circumferential pressure, hence the wearer's freedom of movement is in no way restricted. There is no cramping or binding of the hips. It is light in weight, and easy to apply. There are no complicated fastenings.

IN USE IN MOST OF THE LONDON HOSPITALS.

SALT'S COLOSTOMY BELT

with sterilizable Rubber Cup

(Registered Pat. No. 749046)

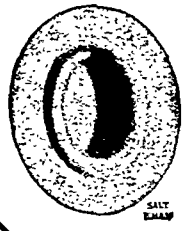
EMBODIES THESE VITAL POINTS

1. Detachable Cup sterilizable by boiling, repeatedly without deterioration.
2. No crevices or metal fittings to hold faeces.
3. *Smell reduced to a minimum.*
4. Minimum of bulk.
5. Cups easily and economically replaced.

This belt can also be provided with Bag instead of special cup.

This belt is specially designed for cases where faeces are of a solid nature or the amount is small.

The special feature is the Cup, which is made of moulded rubber in one piece, having no corners or crevices and therefore does not retain the odour.



View of Cup showing moulded rubber pad which fits snugly against the body.

Side view of Cup. The Cup flange and circular pad are made as one moulding.

"VARIBAN"

Elastic Plaster BANDAGE

MADE from a specially woven selvedge material, possessing very elastic properties, evenly spread with an Antiseptic Zinc Oxide Paste. Self-adhesive, readily conforming to the shape of the limb, and when carefully applied forms an even surface dressing which will not crease or slip. Firm support. Easy to remove. Extensively used in many well-known hospitals for the treatment of VARICOSE ULCERS, VARICOSE VEINS, SURGICAL and ORTHOPAEDIC CASES, etc. Their application for treatment of Varicose Ulcers, etc., does not necessitate the patient lying-up; in fact, permits the *continuance of light duties. Ensures rapid healing.*

To Relieve Chronic Intestinal Stasis in Women

When you have a patient with chronic intestinal stasis due to diminished tonicity and stretching of abdominal muscles following a pregnancy, you will obtain excellent results from the mechanical support provided by a Spencer Belt.

Equally satisfactory results are obtained by the use of a Spencer Abdominal Belt for cases where atrophy and diminished tonicity are due to toxaemia and loss of fat following a severe illness or an abdominal operation, or in any case where enteroptosis exists.

The back of the Spencer Belt is made long enough for comfort, and to provide adequate back support.

SPENCER BELT.

The front of the garment curves in snugly to the pubic bone, and is so designed and adjusted that it uplifts the abdomen instead of compressing it.

Spencer Belts to relieve chronic intestinal stasis will be provided with ptosis pads if the physician desires it.

Each Spencer Belt is designed to meet the special needs of the individual who will wear it. You can therefore prescribe and obtain exactly what your patient needs.

The Spencer Corsetière will call at your surgery or at your patient's home to take measurements under your supervision.

We issue booklets on the use of Spencer Supports for the relief of enteroptosis, hernia, movable kidney, sacro-iliac strain, and for maternity wear. We will gladly send you any in which you are interested.

RELIEVES RHEUMATISM

Samples for clinical trial will be forwarded on request to duly qualified members of the medical profession on application to Bristol-Myers Company.

The toxic amino-acids present in the system as the result of non-regular and imperfect evacuation give rise to rheumatism and other kindred complaints. Sal Hepatica swiftly and painlessly stimulates to peristaltic activity, ensuring complete and satisfactory elimination of all systemic poisons and waste products. Sal Hepatica induces a free biliary flow; hence its regular usage does not lead to a condition of tolerance. Sal Hepatica alkalizes the system and reduces blood pressure and as a result promptly relieves pain and distress in rheumatic conditions.

Sal Hepatica contains sodium sulphate, sodium phosphate, sodium chloride and lithia citrate in effervescent medium.

Sal Hepatica

the proved, medicinal, saline laxative and cholagogue.

MAXILLARY SINUSITIS.

Typical Case.

L. M., female, aged 24 years.

Diagnosis: Right maxillary sinusitis.

Operation: Denker's operation with drainage.

Anaesthesia: Maxillary nerve block with 22 c.c. 1 per cent. Novocain-Adrenaline.

Operation: The needle was introduced at a point 2 cm. posterior to the external canthus of the eye, just below the zygoma. Paraesthesia was felt in the right side of the face and 2 c.c. of a 2 per cent. Novocain-Adrenaline solution was injected. Within a minute towel-pins could be placed upon the lip. The lip was retracted and the sinus opened, curetted, and drained without the production of pain.

—EXTRACT from PRACTICAL LOCAL ANAESTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anaesthesia will be found in the above work, published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANAESTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify "Novocain" for your next operation.

Does not contain Cocaine, and does not come under the Dangerous Drugs Act.

OVALTINE

IN GALACTOSIS

Diet in lactation is a matter of no less importance than diet during pregnancy.

"Ovaltine" completely meets the requirements of the diet of the nursing mother by providing adequate and appropriate nourishment.

It is easily digested, wholly nourishing, and does not convey any noxious or unpalatable substances to the breast milk. For these reasons "Ovaltine" will be found a most dependable prescription for establishing galactosis.

"Ovaltine" is recommended to be given about the sixth month of gestation and should be continued throughout the nursing period. A rich milk secretion is thus encouraged and the health of the patient safeguarded against overstrain.

As an example of the nutritive power of "Ovaltine" it may be stated that one cupful yields more nourishment than 3 eggs or twelve cups of beef-tea.

A liberal supply for clinical trial sent free on request.

TO COUNTER ACIDOSIS

As SALVITAE contains 59% of Potassii et Sodii Citro-Tartras and 30% of Sodii Sulphas it is of great value both in maintaining health and in the treatment of disease, through eliminating deleterious nitrogenous products and favourably influencing circulation, glandular secretions, peristalsis, and metabolism.

The fruit acids of SALVITAE are converted in the system into potentially basic alkaline carbonates, thus enabling the blood to keep the uric acid compounds in solution, and facilitate their removal.

Proverbs Up-to-date No. 5

CLEANLINESS IS NEXT TO GODLINESS

In cleanliness lies the key-note of success on the Preventive side of Dentistry. Many manifestations of Oral Disease and Dental Caries are due (either as a direct or contributary cause) to the effects of accumulations of extraneous matter and food debris around the teeth. If these are removed regularly, and the teeth themselves kept polished, such a state of constant cleanliness can be maintained in the mouth, that much dental trouble can be avoided.

These are the truths that are given such widespread publicity and force in all Gibbs National Advertising. Gibbs constantly remind the public that a little care and thoughtfulness in matters of dental hygiene is repaid a thousandfold in the preservation of the teeth, freedom from suffering and improvement in health.

Wherever the public is urged to use Gibbs Dentifrice twice-a-day, the phrase is complemented by the advice to visit the Dentist twice a year.

Always, in Gibbs propaganda, the Doctor and Dentist are represented as the highest authorities on all matters affecting the teeth; and as a result there is an increasing acceptance upon the part of the public of any advice or instruction given by Doctors and Dentists.

GIBBS DENTURE TABLET

Gibbs new Denture Tablet is for cleaning Dental Plates (both gold and vulcanite), Bridgework and artificial teeth. It gives a high polish, removes stains, makes plate or teeth sterile and antiseptic without in any way injuring the softest gold or the finest vulcanite or platinum. The formula has been submitted to and approved by important members of the Medical Profession.

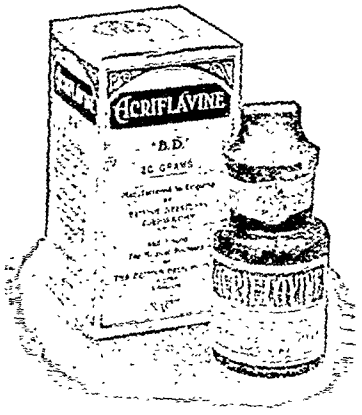
BOOTS PURE DRUG CO. LTD., NOTTINGHAM.



'Acriflavine . . . . . one of the safest and as near the ideal antiseptic as at present obtainable.'

Acriflavine approaches so nearly to *'the ideal antiseptic'* because in it are combined high antiseptic power and non-toxicity; in fact, in dilutions at which it is highly toxic to pathogenic bacteria, it is practically non-irritant to mucous tissues.

Acriflavine 'B.D.'—the original British brand of Acriflavine—possesses all the advantages of the ideal antiseptic on account of its purity and efficacy.

It is issued in powder form, also in tablets, in solution, in an ointment, in bougies and in suppositories.

To obtain the original British Acriflavine, 'B.D.' brand should be specified.

HORLICK'S MALTED MILK

has played a successful part in infant feeding for many years. From various causes it is not possible for every mother to breast-feed her child, and artificial feeding must be resorted to. Very many infants, however, cannot and do not thrive on the ordinary modifications of cow's milk, and for such HORLICK'S MALTED MILK may be confidently recommended. Made from full-cream cow's milk and the nutritive extracts of malted barley and wheat, it is entirely free from starch, which is replaced by the natural sugars, maltose and dextrin. These are easily assimilated, and are especially suitable in cases where high sugar feeding is necessary, or where there is any degree of fat intolerance. The casein is so modified that, on coming into contact with the acid gastric juice, only light flocculent curds are formed similar to those given by human milk. HORLICK'S is a modified milk food, which is especially suitable to meet the needs of premature, delicate, or under-nourished children.

PHYSIOLOGICAL TREATMENT OF CONSTIPATION

COMPOSED OF

EXTRACT OF THE INTESTINAL GLANDS

which strengthens the glandular secretions of the organs.

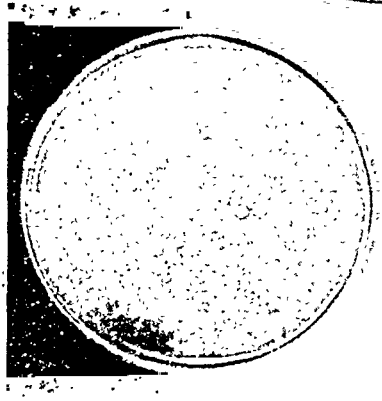
BETTER MILK FOR BABIES

ORDINARY MILK

1/1,000 c.c. plated—over 200,000 bacteria per c.c.

FACTS ABOUT **LACTOGEN**



Purity

Lactogen is under hygienic and scientific control from the time the raw milk is collected until the despatch of the finished product.

The fresh milk used for its preparation is obtained from selected farms, the herds receiving close supervision from the Company's farm inspectors.

A stringent examination is also carried out in the factory laboratory, and with these precautions a constant high degree of purity is maintained.

The modern manufacturing process is carried out under the most strictly hygienic conditions, and the bacterial count of Lactogen, as reconstituted, is less than 100 organisms per c.c.

Lactogen is neither a new nor untried product. First introduced in Australia, it has for many years enjoyed a large sale in overseas countries.

LACTOGEN
Full strength mixture.

THE SUPERIORITY OF COD LIVER OIL AS A CURE FOR RICKETS

Leading Authorities have proved by the most painstaking researches that:

A certain number of D-vitamin units in the form of Cod Liver Oil is far more effective in the treatment of human Rickets than the same or even double the number of these units in the form of irradiated Ergosterol.

Read what Professor E. Poulsson says on the subject in his recent paper "On the Action of Cod Liver Oil and Irradiated Preparations in Rickets", published by the State Vitamin Institute in Oslo.

This paper may be obtained free by post on application to the State Vitamin Institute.

The world-renowned Norwegian Cod Liver Oil has always been noted for its high quality. Exported under control of the Norwegian State.

THE PROPHYLAXIS AND TREATMENT OF

HAY FEVER

The rapid onset of the adrenalin effect of EPHREGEL NASAL JELLY is usefully supplemented by the prolonged action of the ephedrine, and this is still further enhanced by the water-soluble base in which the ingredients are incorporated. It is eminently suitable for the reduction of congestion of the mucous membrane of the nose in Hay Fever, Rhinitis, etc.

Issued in Collapsible Tubes, fitted with nozzle.

Many practitioners prefer a Nasal Spray such as EPHRESOL, a solution incorporating with Ephedrine useful medicaments which accentuate its beneficial effects.

Issued in 1-oz. bottles.

BACTERIAL VACCINES are sometimes beneficial during an attack of Hay Fever. We have had reported to us numerous cases where the use of our "Common Cold" Vaccine, administered in small doses, has given satisfactory results, reducing the severity of the attacks, no doubt by dealing with the accompanying infections.

MAP SHOWING THE DOMINIONS OF THE VISIGOTHS DURING THE FIFTH CENTURY A.D.—Pressed by the Huns, the Visigoths surged southwards into the Roman Empire where, during an uncertain period, they were sometimes the enemies and sometimes the confederates of the Romans. Under Alaric they sacked Rome, but after the death of this leader they turned north and passed into Gaul and Spain, where, under Athaulf and his successors, they formed a powerful kingdom. In Gaul they founded the kingdom of Toulouse in the region of which this city was the capital; it expanded at the expense of the Roman Empire until it reached the extent indicated on the accompanying map. In Spain the kingdom grew until it covered all but the north-western corner, which the Suevi succeeded in retaining. The nation, founded in the first decade of the fifth century, lasted in Gaul until 507, when it fell before the Franks under Clovis, and in Spain until it was succeeded by that of the Islamic Arabs in 711.

RHEUMATOID and OSTEO-ARTHRITIS

Amidst the recognised difficulties in treatment of advanced cases of Rheumatoid and Osteo-Arthritis it is not generally realized that many patients have been restored to active life after being bedridden, suffering great pain for years, by Hoefftcke's Ambulatory Extension Treatment.

Many cases have been described by eminent medical men, some results of which are shown below.

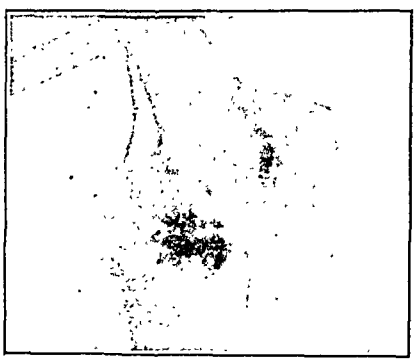

FIG. 1.—December, 1921.

Case of Mrs. H., aet. 35.

FIG. 1.—Shows the knee-joint fixed in a position of *partial flexion; patella ankylosed.*

FIG. 2. — Shows after an interval of 9 years the improvement which resulted from 3 years' extension treatment—the complete restoration of the tibio-femoral joint which permits of free and painless flexion and extension.

This case was one of exceptional severity. In the average case the Extension Walking Appliance can be discarded in one or two years from the time of its first application.

FIG. 2.—April, 1930.

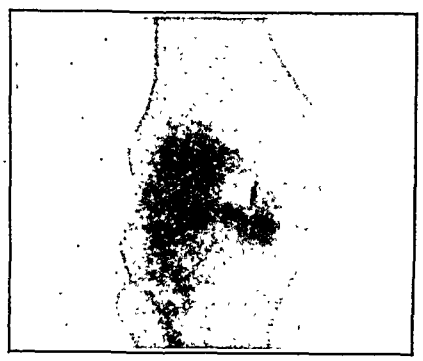

FIG. 3.—December, 1921.

FIG. 3.—Shows the irregularity of the outline of the articular surfaces as seen *from before backwards.* The interval between the bones is practically obliterated.

FIG. 4.—Shows the joint in an antero-posterior plane. Note the restoration of the outlines of the articular surfaces and the formation of a practically normal interval between the bones.

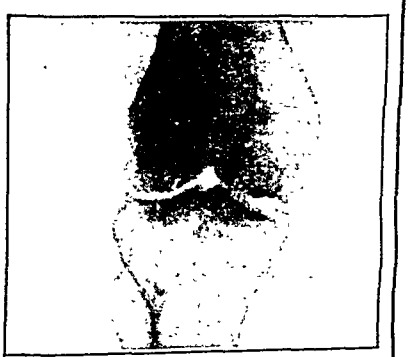

FIG. 4.—April, 1930.

FIG. 5.—July, 1929.

Case of Mr. S., aet. 68.

FIG. 5.—Shows the hip-joint practically ankylosed in the adducted position. Patient hardly able to walk with great pain.

FIG. 6. — Shows spike absorbed; cavity filled in; head of femur covered with new cartilage, resulting in free abduction with full painless movement in the joint.

FIG. 6.—February, 1931.

Particulars and illustrations of this treatment will be forwarded on application, and original radiograms of these and other cases can be shown

Remarks
ON
TREATMENT OF RECENT SIMPLE FRACTURES OF THE LONG BONES*.

BY
C. H. FAGGE, F.R.C.S.
SURGEON TO GUY'S HOSPITAL

I feel that I need make no apology for my choice of subject. I have been consulted several times by medical men in great distress owing to some alleged mishap in the treatment of a fracture for which legal action was threatened; such an occasion has never arisen in relation to any other disease or injury. Therefore it is, I hope, superfluous to advise everyone to join a protection society, or to suggest that in every case *x*-ray examination must be insisted upon before, during, and after treatment. Objection by the patient to the latter should be obtained in writing.

REDUCTION OF DEFORMITY

In fractures the aim of treatment is the restitution of the bone and the function of the limb to normality. It is true that a degree of function, indistinguishable from the normal, may be restored when anatomical alignment is imperfect, but the better the anatomical reposition the better the function, so that the surest way to re-establish function is to obtain perfect anatomical replacement. The necessity for this varies with different factors; it is less essential in the young than in the old, for in the former, in accordance with Wolff's law, if the body weight is transmitted along a new line, the bone outline is remodelled to accommodate itself to the direction of that force. Where a stress is exerted bone is laid down; where there is strain it is absorbed.

Deformity is of more consequence in its relation to function in certain bones than in others; thus angulation, which is easily compensated for after a fractured femur, will lead to serious depreciation of function if it results from a fracture of the tibia. As an enormous majority of the fractures of the long bones occur below the knee, realization of this depreciation is of great economic importance. Ashhurst[1] suggests that the explanation lies in the fact that the tibia is the only long bone which is limited at either end by joints moving in only one (and that a similar) plane, so that very little compensation is possible.

A degree of angulation which is of little harm near the middle of a bone produces a greater defect near the articular end, and in certain bones certain deformities —often in one direction only—are particularly depreciatory; thus adduction after a fracture of the shaft of the femur not only adds apparent shortening to the real shortening, but also produces secondary changes in the spine and other joints. Of the displacements to which a fracture is liable, shortening is relatively unimportant, compared with angulation or rotation. A particular angulation or rotation at any level may produce a more serious depreciation than its opposite; thus angulation inwards after a fracture of both bones of the leg will predispose to talipes valgus and knee strain, but a similar degree of angulation outwards will not be so serious. Again, rotation inwards of the femoral shaft below a fracture is a more serious, if rarer, handicap than rotation outwards.

As a routine, reduction of deformity is obtained under a general anaesthetic (gas is not sufficient). This setting of the fracture, which one hundred years ago was rightly regarded as all-important, had some years ago fallen from grace, and it was not until the British Medical Association's Fracture Report of 1912 entirely upheld Lane's contention that anatomical reposition was essential that surgeons really took it in hand as a routine.

What are the obstacles which have to be overcome in order to eliminate deformity?

1. The most important is the position and size of one fragment, which is so often small, and so placed that one cannot by any conceivable means, externally applied, bring influence to bear on it, particularly when there is an associated dislocation.

2. Intervention of soft parts—for example, (*a*) a mass of brachialis anticus in fractures of the lower humeral shaft; (*b*) a sharp fragment of tibia penetrating the deep fascia of the leg and caught so that it cannot be withdrawn. Less commonly a similar evil influence may be effected by penetration of periosteum.

3. When one of two parallel bones is fractured the other normal bone acts as a splint and opposes reduction.

It would take too much time to give even an outline of the various manipulations required to reduce deformities in the different fractures of the long bones; each conforms to certain general rules—namely:

(1) Exaggerate the deformity to release the broken ends; (2) carry out the movements reversed by which the fracture was produced. (It is only when one begins to consider what these movements should be that one realizes how difficult it is to conceive the mechanics of the production of any fracture.)

When alignment has been restored its maintenance may be rendered difficult by obliquity of the fracture, comminution, or the action of gravity. I doubt whether muscular pull is a factor of appreciable importance. When any one of the above tends to favour the recurrence of deformity, care must be taken that immobilization is complete, and for this purpose plaster-of-Paris has no rival. The endeavour to restore alignment is checked by a radiogram in two planes or, better still, by stereos. Meanwhile the fracture has been immobilized. If the *x* rays show that the deformity has been reduced—completely, or to a degree sufficient to meet the circumstances of that particular case—immobilization is continued for such time as is necessary to ensure firm osseous union.

In regard to the position in which any fracture should be immobilized, there is in my opinion only one general rule—namely, that the limb should be fixed in a position favourable to muscles which act against gravity. Thus all fractures of the bones of the forearm should be immobilized in a position of full supination, for the supinators act against gravity, and this is the movement most often impaired or lost after such fractures. The old dictum about the influence of the level of the fracture in relation to the insertion of muscles is ignored.

For fractures near the shoulder the abductors must be relaxed, and so the arm is fixed in abduction on an aeroplane splint, or in a plaster case. To this generalization, however, there must be a limitation, which is that there is no hard-and-fast rule for the position of immobilization for every fracture of any bone at any particular spot; this opinion can be verified by screening the patient at the time of setting the fracture, when it will be seen that each fracture has its optimum position. This, it is true, is usually only a slight variant of the routine position, and can, I suppose, be explained by a slight variation in the plane of action of the force causing the fracture. No "splint" can be relied upon to procure reduction of deformity, but some "splints" are capable of maintaining that reduction when it has been obtained by manipulation. Such "splints" are plaster cases, and some form of Thomas's splint, with or without axial traction. I cannot think of any fracture in any position in which the application of a wooden splint is the best line of treatment. In my practice, after the deformity has been reduced, the limb splinted, and the fracture *x*-rayed in two planes, it is decided whether the reduction

* A paper read at a meeting of the Kent Branch of the British Medical Association.

is satisfactory. If it is not, the procedure is usually repeated, but if those responsible for this part of the treatment are certain that no amount of manipulation will produce any better effect, then a Steinmann's needle or Kirschner's wire is inserted for the purpose of securing and maintaining reduction of deformity by axial traction.

TRACTION AND IMMOBILIZING APPARATUS

When, for the purpose of such a paper as this, one comes to ask oneself what one has done, and how long one has used a particular apparatus, it is difficult to be sure of dates; but I think I have used this kind of treatment with success since the war, when I began with Beasley's ice-tong callipers for the femur, but this apparatus was soon discarded. I have little to complain of in regard to Steinmann's needle, but it makes, perhaps, an unnecessarily large hole in the bone: it has been my habit, when traction is needed for the treatment of a fractured femur, unless the fracture extends into the knee-joint, to insert it through the femoral condyles. Some surgeons object to this and perforate the tibia, but as this tends to displace the upper end of the lower femoral fragment backwards, it does not please me. In one case of fractured femur treated with a pin a sinus persisted, and there was limitation of flexion to a right angle until the sinus was scraped out, when all went well. Otherwise I have not seen any limitation of movement from its use, which has this great advantage over its introduction into the tibia, that it allows of movements of the knee during treatment. For fractures of the lower third of the tibia, in which position its effects are almost miraculous, the needle is passed through the os calcis at such a spot as to be nearly in the axis of the ankle-joint when looked at from the side. The use of Kirschner's wire is now replacing a pin. Some 10 to 30 lb. weight is used over a pulley, and a word of caution is necessary, because the wire with a heavy weight may cut through soft cancellous bone as if it were cheese. This method of axial traction is a great advance in the treatment of just those fractures which are so difficult to treat by other means (Figs. 1 to 8). Traction is rarely necessary for more than three to four weeks, for by the time this period has passed the relation of the fragments to one another is fixed by callus still too soft for weight-bearing, but not likely to allow recurrence of deformity if traction is dispensed with.

When the traction apparatus has been applied the fracture is again radiographed in two planes with the portable apparatus. If reposition is not satisfactory, it may be possible to improve matters by altering weights or by a second manipulation under an anaesthetic. I wish to insist that whatever type of immobilizing apparatus it is decided to use, the position of the fragments must be checked after the apparatus has been applied. Nothing but a miracle can improve the position after the apparatus has been put on, and miracles do not occur. On the other hand, the position will often alter for the worse, particularly if we rely on such inefficient methods of immobilization as wooden splints and do not check our results with repeated *x*-ray examinations in two planes.

OPEN OPERATION

Sometimes even now the restoration of anatomical normality is not good enough. The degree of reposition necessary is a matter of opinion, and this will vary with different surgeons; but when it is clear that reposition is not satisfactory, an open operation must be considered at once. It is usual to arrive at this point at which manipulation and traction has failed within ten days of the accident. Whenever I have been in doubt about the necessity for an open operation and have decided against it, I have regretted it afterwards; I do not recall a disappointment of a converse nature. At any rate, even under the most unfavourable circumstances we should know within fourteen days of the accident whether a good anatomical result can be obtained by non-operative means.

If we persist without operation the result will be either (1) malunion, or (2) non-union. Both these conditions are preventable. The probability of non-union can be surmised from the fact that reposition of a fracture by manipulation is impossible; this suggests the intervention of soft parts between the fragments. It is usually confirmed by the *x* rays, which show at each stage an appreciable interval between the fractured ends of the bone (Figs. 9 to 14).

As has already been pointed out, malunion after fractures of certain bones is of greater economic importance than malunion after fracture of others, but in any case if its degree is going to be such that an operation would later be necessary it should not be allowed to occur. Early operation to prevent malunion is far easier and will obtain an infinitely better result than one undertaken after eight to twelve weeks; in fact, the longer the delay the less perfect will the result be. There is only one sound treatment for potential malunion, and this is prevention. Prevention is always possible. The doctor treating the fracture should know within fourteen days of the accident that treatment by means at his disposal must be followed by an imperfect result, and he has still a week and perhaps more—but I prefer to be dogmatic in my time limit—in which to call in a surgeon with experience of operations on fractures.

Open operation of one type or another, when really necessary, will, if undertaken within three weeks of the date of the accident, usually give a result which is serviceable; at any rate it will be vastly better than that obtainable by non-operative treatment. I want to say most emphatically, as a generalization, that, in my opinion, doctors looking after fractures are responsible for the bad results comprised under non-union and malunion, for they fail to realize until too late that non-operative treatment is futile. There is no comparison between the difficulty and labour—mental and bodily—of an operation on a fractured long bone undertaken in the first three weeks, and an operation on the same case undertaken for non-union when the bone ends have become rounded off and the medulla closed, or for malunion when there is firm side-to-side union, and the surrounding muscles have shortened.

I would urge again, at the risk of unnecessary repetition, that a decision must be arrived at in the supervision of any simple fracture of a long bone that non-operative treatment will give a satisfactory anatomical result, and therefore a good functional one. If the answer is doubtful or in the negative, operative treatment must be considered *at once*, for only at that time can it be of the optimum value to the patient. Now in quite a large percentage of fractures for which operation should, in my judgement, be undertaken, all that is necessary is the restoration of alignment under direct vision through an open incision. This is particularly true of transcondylar or supracondylar fractures of the lower end of the humerus, in all their different types (Figs. 15 and 16); also in fractures of one bone of the leg or forearm when the other bone is unbroken (Figs. 17 to 20) and in fractures involving articular surfaces (Figs. 21 to 31).

Fractures Involving Joints

I must emphasize my belief in a fact which has not been sufficiently stressed, that open operation must be undertaken for fractures involving joints. In these, as a rule, a small articular fragment is knocked off and lies free in the joint cavity. Because in a child it largely consists of cartilage, its size is greater than the *x* rays suggest, and it is impossible to guess in what direction its articular

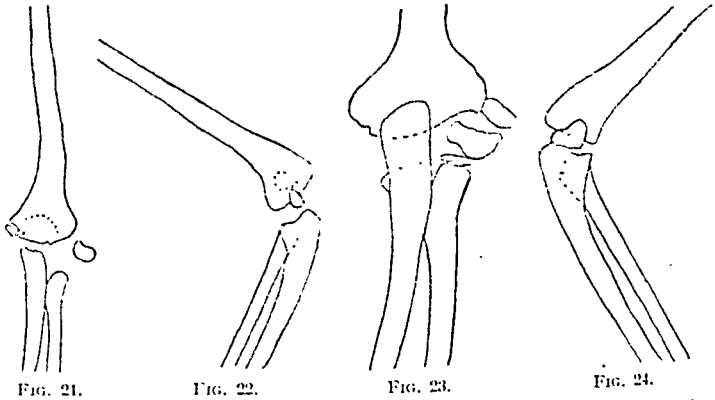
surface has been turned (Figs. 21 to 24; 25 to 27; 28 to 31). When one femoral condyle, or a considerable proportion of any articular surface, becomes detached, open operation is usually imperative for a different reason. In this case the extent of the displacement of the detached condyle may be estimated by the greater depth of the joint cavity on the affected side; wherever possible such a displacement must be corrected, for displacement of part of the articular surface means that the mechanics of the joint are altered and chronic traumatic arthritis is in time certain to supervene.

Open reposition is valuable when dealing with a separation of an epiphysis (Figs. 32 and 33). It is particularly needed when the small fragment includes a wedge of the diaphysis, for this seems to impede reduction.

In dealing with articular fractures, if the detached fragments will not, when reduced, remain in correct position, they can usually be secured by sutures through the soft parts (Figs. 21 to 24) or fixed with a pin or screw (Figs. 25 to 31); at the worst they must be removed. It is my present purpose to insist that open operation does not in a majority of cases necessitate the introduction of an internal unabsorbable splint.



FIGS. 21, 22, 23, AND 24.—S. F., aged 10. Fracture of capitellum and external condyle of humerus. Figs. 23 and 24. Replaced by open operation. Fragment replaced by catgut sutures.

Experience of setting fractures by open operation reveals several facts of interest. The first is that it is the rule rather than the exception to discover conditions which could not have been corrected by manipulation—for example, the sharp end of one fragment may be driven through the deep fascia, or one end may be buried in a mass of muscle from which, even when explored, it cannot be released without free incision.

My second observation is of greater importance, and, to me, of greater interest. It has been demonstrable in almost every case in which I have done an open reposition. The last time I demonstrated it to my Firm was when operating upon an articular fracture of the humerus, involving the capitellum and half the trochlea (Figs. 21 to 24). It is that if reduction is perfect the posture in which the arm is immobilized is immaterial; when anatomical reposition has been secured there is usually so close an apposition of the irregular fractured surfaces that a force applied to the hand does not cause these surfaces to move on one another, but acts upon the elbow-joint, where the resistance to movement is less than at the fracture. This observation confirms what I have written on several occasions and have taught for years—namely, that if one carries out the reduction of such fractures under an anaesthetic on an *x*-ray table, one can see that, after reduction, the rough surfaces of the fracture so intermesh as to resist the recurrence of deformity, and if one now flexes and extends the elbow the deformity will not recur within certain limits, which are wider the more transverse the line of the fracture. As a rule, reposition is maintained perfectly at a right angle, and what is known as the Jones's position is quite unnecessary. This is a matter for congratulation, for, in the experience of most surgeons, immobilization of the elbow in acute flexion incurs a grave risk of ischaemic palsy. Sir Robert Jones[2] writes that he has advocated treatment of "all these lesions by manipulation, followed by slinging the arm at about 30 degrees of flexion. . . . This should be carried out even in the presence of considerable swelling. . . . Flexion is the correct position in all injuries to the region of the elbow excepting fracture of the olecranon." No reasons are given for these *ex cathedra* statements. I assert without fear of contradiction that posture cannot be relied upon to reduce deformity (and I feel sure from the

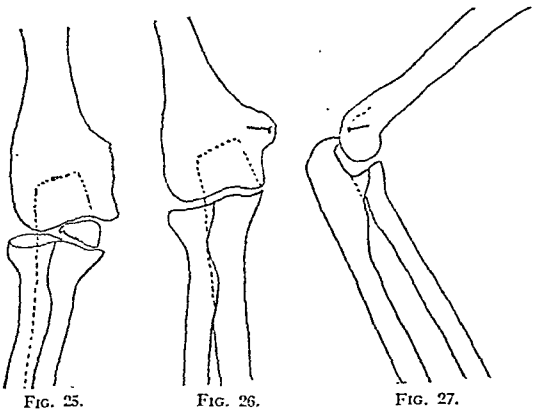


FIG. 25. FIG. 26. FIG. 27.

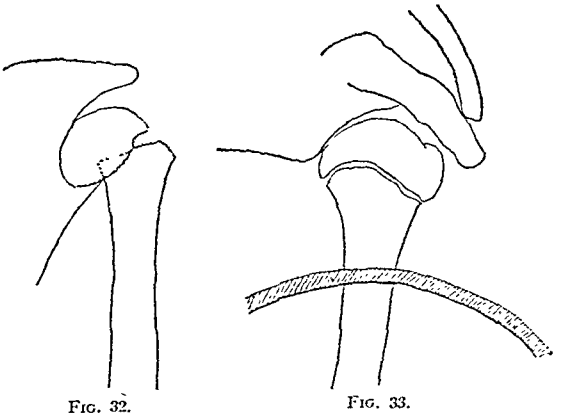

FIG. 32. FIG. 33.

FIGS. 32 AND 33.—S. S., aged 13. Separated upper epiphysis of humerus. Fig. 32. After failure to reduce by manipulation. Fig. 33. After reduction by open operation.

context that Sir Robert Jones has insisted on this for years); I also hold that if deformity is reduced there is no one position, and one only, in which reduction can be maintained.

I do not ask that one word of what I say should be taken for granted. I suggest to any surgeon, when next he has to treat a transcondylar fracture of the humerus in a child, that he should reduce it under an anaesthetic on the *x*-ray table, that he check his reduction by the screen, and then, if reduction is reasonable, see what effect flexion or extension has on the fracture. I am content to leave my point of view to be confirmed or refuted by such ocular demonstration. In my experience, founded on what I have seen on the operating table and on the *x*-ray table, the position advocated by Sir Robert Jones is both unnecessary and harmful.

A recent action against a surgeon concerned a transcondylar fracture of the humerus in a child who was taken to him immediately after an accident. He had the part radiographed, and proceeded to reduce the deformity, putting the elbow up in full flexion. The injury and manipulation, etc., were naturally followed by swelling, and, though the flexion was released, Volkmann's contracture followed from fibrosis of the flexor muscles of the forearm. The cause of this is generally believed to be obliteration of the vascular supply to these muscles from a degree of flexion which is too great for the particular case. The usual safeguard relied upon is the radial pulse, but this is not infallible. Local pain in the forearm at once demands release of flexion, but in my opinion manipulation and fixation in full flexion should *never* be undertaken until the maximum swelling resulting from the fracture has occurred, though as a fact my teaching has been, for the reasons given above, that full flexion is never or very rarely necessary.

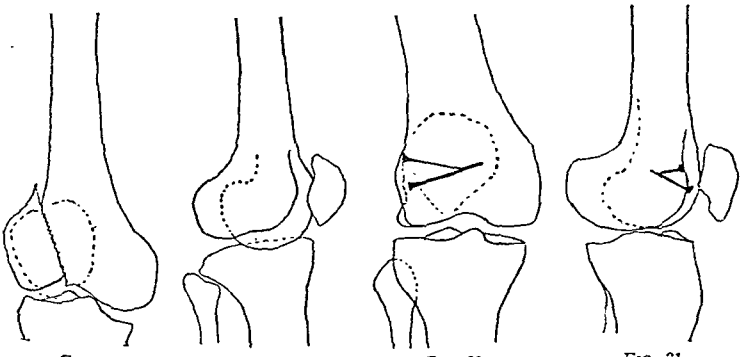

FIG. 28. FIG. 29. FIG. 30. FIG. 31.

FIGS. 28, 29, 30, AND 31.—A. S., aged 21. Fracture of external femoral condyle. Replaced by open operation and fixed with screws.

AFTER-TREATMENT

With regard to after-treatment it must be borne in mind that the surgeon has not carried out his task until complete function has been restored. The commonest minor complaint of a patient with a recently fractured leg is that of swelling; this is favourably influenced by massage, and exercises undoubtedly hasten the return of normal joint movements. At the same time it must be remarked that massage does nothing which nature will not do, but it does it more quickly; attendance at massage departments entails expenditure of time and money, which, in my judgement, is often ill repaid. I see no use in any ordinary case for passive movements.

When bony union is, after some four to six weeks, reasonably assured, active movements of joints without resistance or weight-bearing should be encouraged. In the practice of some, this is done at a much earlier stage, but I must admit that my practice tends to err on the side of ensuring union. This is the first essential, as in my view there is by a more prolonged immobilization no hazard to return of complete movement, though this may be delayed thereby.

I do not use passive movements in the treatment of a recent fracture. Those who employ them with success may pity me, but I have seen bad effects produced by ill-restrained passive movements oftener than anything else; the director of our massage department has forbidden them unless specially ordered.

As a routine for a fracture of the thigh six weeks in a splint is followed by six weeks in a calliper, and then weight-bearing is allowed; for a fracture of the leg eight weeks will suffice, but in neither case must weight-bearing be allowed until *x*-ray evidence confirms the clinical signs of union; this precaution is rather for legal protection

than for the information it conveys, for not infrequently union is firm to clinical tests some weeks before it is confirmed radiologically. This third *x*-ray depicts the anatomical result, but nothing less than a film will disclose the restoration of function, and even this does not record the various aches and pains which may impair a perfect result.

It is strange that public opinion on the treatment of fractures is that anything short of perfection indicates incompetence or negligence, and yet a much greater margin of error is given to us in the treatment of almost any disease. But most of the latter tend to get well, and in some fractures, particularly if occurring after middle life, we cannot anticipate more than a fair result.

COMBINED USE OF LIVING VIRUS AND IMMUNE SERUM FOR IMMUNIZATION AGAINST VIRUS INFECTIONS

BY

G. M. FINDLAY, O.B.E., M.D., D.Sc.Ed.

AND

E. HINDLE, Sc.D.Camb.

BRIT. RESEARCH FELLOW IN TROPICAL MEDICINE

(From the Wellcome Bureau of Scientific Research, London)

None of the methods at present employed in immunization against virus infections is completely satisfactory. Since the time of Jenner it has been recognized that the use of a virus attenuated by passage through another animal species can confer a high degree of immunity. Nevertheless, the employment of such an attenuated virus may not be entirely free from danger, as is shown by the occasional occurrence of an encephalitis after inoculation with vaccinia virus. Whether due to the vaccinia itself or to some other associated virus, the encephalitis appears to be initiated by the lesions produced as a result of the local inoculation of the vaccinia virus, and in order to minimize these lesions a single inoculation, with a minimum of trauma in place of the customary four insertions, has been officially recommended (Ministry of Health, Committee on Vaccination, 1928).

Various other methods of immunization have been tested, in particular those involving the use of virus attenuated by chemical means. Although these vaccines have given good results in dog distemper (Laidlaw and Dunkin, 1926 and 1928), rinderpest (Curasson and Delpy, 1926; Kelser, 1927), fowl pest (Todd, 1928), and yellow fever (Hindle, 1929), there are certain technical difficulties in their preparation. One of the chief of these is the absence of any reliable method of standardization, so that vaccines of varying degrees of potency are obtained, and it is impossible to titrate them even approximately, except by making numerous animal experiments. Moreover, in dog distemper it has been found advisable to reinforce the immunity following vaccination by a subsequent injection of living virus, a procedure fraught with many technical difficulties, and only possible in the case of animals, since any failure in the potency of the vaccine must certainly result in a generalized infection.

The nature of these vaccines is still under discussion, but there is strong evidence in support of the view that many of them must contain living virus. Up to the present, all attempts to prove the existence of live virus in yellow fever vaccines have given negative results, nor does the blood of vaccinated monkeys become infective to mosquitos. However, the possibility of such an eventuality cannot be entirely ignored.

Immune or hyperimmune serum has been advocated in certain virus diseases, and in particular has been employed for protection against yellow fever. Although this method possesses the advantage of producing an immediate effect, in contrast with vaccines which require at least several days before conferring any protection on the subject, it has the great disadvantage of producing only a temporary immunity instead of the more durable protection conferred by vaccines. The results obtained by the use of immune serum in yellow fever are discussed below; they indicate that, as a general rule, this passive immunity rarely persists for more than a few weeks; similar results have been obtained in rinderpest and hog cholera. Yet another method of protection is obtained by a combination of immune or hyperimmune serum and virus, which has been used for immunization against both rinderpest (Kolle and Turner, 1898), and hog cholera (Dorset, Bolton, and McBryde, 1904). In the case of rinderpest the animals were inoculated on one side of the rump with immune serum, and on the other side with virus. Some individuals reacted with a fever, and their blood became infective, and about 1 per cent. died of the disease; the application, therefore, of this method in rinderpest is restricted to heavily infected localities. A further difficulty has been the risk of infecting with piroplasmosis or trypanosomiasis. In the case of hog cholera the use of immune serum produces a passive immunity of about three weeks' duration, but if combined with virus confers an active immunity which lasts for at least six months, and probably longer. The inoculated animals may show virus in the blood, and numerous deaths have been recorded, especially in the earlier experiments. Probably many of these earlier fatalities may be attributed to faulty technique, for later observers—for example, Hutyra and Köves, 1916—tested the method in Hungary and immunized 20,000 hogs, with very slight losses, or no losses at all.

Laidlaw and Dunkin (1931) have recently found that while mixtures of virus and immune serum injected together do not establish immunity, the injection of serum and virus simultaneously side by side does confer durable immunity. So far as we are aware this method has not hitherto been applied in any human infection. Unquestionably, very great care would have to be exercised before it could be generally employed in such a fatal disease as yellow fever, but by the use of immune or hyperimmune serum of proved value there would seem to be very little likelihood of any untoward results. In more benign infections, such as vaccinia, a combination of immune serum and virus, if equally efficacious in producing immunity, would have many advantages over ordinary vaccination, since, apart from suppressing any local reactions, the occurrence of undesirable after-effects would be greatly lessened.

Consequently, we have made experiments to determine whether a satisfactory degree of immunization might be obtained by the use of this method in two very dissimilar human infections—namely, vaccinia and yellow fever. In these experiments active virus was preferred to attenuated virus or vaccines, as, when combined with immune serum, no local or general reaction was observed, and it seemed likely that a fully active virus would produce a more lasting effect than an attenuated one. This method combines the advantages of giving an immediate protection, as a result of the immune serum, and a lasting effect, probably as a result of certain changes in the tissues of the host produced by the introduction of the living virus.

IMMUNIZATION AGAINST VACCINIA BY HYPERIMMUNE SERUM AND VACCINIA VIRUS

The object of these experiments was to determine whether it is possible, by a careful adjustment of the amount of living vaccinia virus and immune serum injected, to produce immunity in the rabbit in the absence of any general reaction, or of any local reaction at the site of inoculation. There is already considerable evidence to show that such a result is possible. Using a strain of neurovaccinia, Andrewes (1929) found that immune serum given intravenously to rabbits, at the same time as large doses of virus inoculated intradermally, prevented generalization of the vaccinial lesions, although development of the local lesions was practically unaffected. Serum given subcutaneously or intradermally could not be relied on to prevent generalization. Of the rabbits in which generalization was prevented by immune serum, 55 per cent. were subsequently found to be immune.

While the experiments recorded in this paper were in progress, Rhoads (1931) showed that vaccinia virus (neurovaccine) and specific immune serum, mixed in such proportions as to produce no lesions when inoculated intradermally, induced immunity when instilled into the nasal cavities of rabbits. The mixture was also effective when inoculated subcutaneously. Immunity was brought about with a minimum of systemic reaction and no local lesion, though when the mixtures were incompletely neutralized generalized vaccinia resulted. In the rabbits infected intranasally, from three to five instillations were given at intervals of from one to two days, while in the rabbits infected subcutaneously, three inoculations of 2 c.cm. of neutralized mixture were given at intervals of four days.

In the experiments here recorded it was desired to approximate as closely as possible to the conditions applying to routine vaccinations in man. In place of the more active neurovaccine, therefore, ordinary glycerinated calf lymph was used as a source of virus, while the immunizing mixture was inoculated intradermally, four injections being given at the same time, not at intervals of some days.

The hyperimmune serum was prepared in the rabbit by intravenous injections of vaccinia derived from rabbit testicle. Preliminary experiments were undertaken to determine the minimum dilution of the serum which was capable of neutralizing a suspension of vaccinia virus diluted 1 in 20 in saline. The suspension of the vaccinia virus was prepared by adding physiological saline to glycerinated calf lymph, centrifuging for ten minutes to throw down gross particles, and pipetting off the supernatant fluid. Virus suspension, 0.1 c.cm., was then mixed with an equal volume of the immune serum and inoculated intradermally. The highest dilution of the immune serum capable of preventing the development of any local lesion was, as a rule, 1 in 30; though in some rabbits dilutions of 1 in 40 protected, in others dilutions of 1 in 25 only were effective. For the development of immunity by means of a mixture of virus and immune serum, the final dilution of the immune serum selected was 1 in 20, as in six experiments this dilution prevented the development of any local lesions. On the other hand, with lower dilutions experiments showed that the final immunity obtained was much less, while when too high a dilution of serum was used the virus inoculated produced typical vaccinia reactions in the skin, although these lesions were generally less extensive than those produced by the same amount of vaccinia in normal rabbits.

The following is a typical protocol of a successful experiment, in which the quantities of vaccinia virus and immune serum were correctly adjusted.

January 5th, 1931.—Rabbit 117 received four intradermal inoculations of 0.1 c.cm. of a suspension of vaccinia virus diluted 1 in 15 in saline + 0.1 c.cm. of antivaccinia immune serum diluted 1 in 10 in saline. The virus suspension was mixed with the immune serum immediately before the injection.

Rabbit 118 received four intradermal inoculations of 0.1 c.cm. of antivaccinia immune serum diluted 1 in 10 in saline + 0.1 c.cm. of saline.

Rabbit 119 received four intradermal inoculations of 0.1 c.cm. of a suspension of vaccinia virus diluted 1 in 10 in saline + 0.1 c.cm. of saline.

Rabbits 117 and 118 showed no local reaction and no significant rise in temperature. Rabbit 119 developed four typical vaccinial papules.

Five weeks later the three rabbits and a normal control were inoculated intradermally on fresh areas of skin with suspensions of 0.1 c.cm. of glycerinated calf lymph in saline in dilutions of 1 in 10, 1 in 100, 1 in 1,000, and 1 in 10,000.

Rabbits 117 and 118 showed slight hyperaemia eighteen hours later, but no reaction after forty-eight hours; in Rabbit 119 there developed typical vaccinial lesions, except that in a dilution of 1 in 10,000 the reaction was less extensive than in the control.

Similar results were obtained when the period between immunization and the test inoculation was extended to eight weeks.

In a further series of experiments the effect of injecting the immune serum and the virus suspension into different skin areas about 2 inches apart was tested. In order to inhibit the local reaction, however, it was necessary to use a lower dilution of the immune serum, a dilution of 1 in 5 being found suitable. Here again it was possible, without causing any local reaction, to produce by the injection of immune serum and vaccinia virus a degree of immunity equal to that produced by the injection of the same amount of living unneutralized virus.

IMMUNIZATION AGAINST YELLOW FEVER BY IMMUNE SERUM AND YELLOW FEVER VIRUS

It is well known that an attack of yellow fever is followed by a high degree of immunity, and Stokes, Bauer, and Hudson (1928) showed that even 0.1 c.cm. of the serum of a patient who had suffered from a severe attack of the disease was sufficient to protect a rhesus monkey against fatal doses of infected blood and the bites of infected mosquitos; but this passive immunity, produced by the injection of convalescent serum, seems to disappear within a comparatively short time. For example, Marchoux and Simond (1906) found that this protection began to disappear about the twenty-sixth day, and Burke and Davis (1930) record three laboratory cases of yellow fever in which injection of convalescent serum had been given four months, forty days, and twenty-four days respectively before the onset of the disease.

Although all three patients recovered, yellow fever shows such wide variations in its virulence that it is impossible to be certain that recovery was due to the serum. The last patient, who had been injected with 16 c.cm. of human convalescent serum only twenty-four days previously, had the mildest attack, and it seems probable that in his case the serum had some effect, but it is obvious that this method of protection has very limited applications. Apart from the method of immunization, to which we again draw attention in the present publication, the most valuable use of convalescent serum is for the treatment of individuals who have been exposed to infection. In the course of our experiments one of the laboratory attendants, who had certainly been inoculated accidentally with a virulent strain of yellow fever, received an inoculation of 20 c.cm. of human immune serum the following day, and showed no signs of the disease. On the other hand, the inoculation of immune serum after the symptoms have developed seems to have little effect on the course of the disease, as evidenced by the records of various laboratory infections, and also in the treatment of infected monkeys (Hindle, 1929).

The duration of passive immunity in monkeys seems to be of similarly short duration to that in human beings, as shown by the following experiments:

May 8th, 1929.—Rhesus No. 205, inoculated subcutaneously with 0.5 c.cm. citrated blood of an immune monkey, VII 30. Thirty-six days later it was inoculated subcutaneously with 0.05 gram of infected liver and spleen of Monkey 210, and had a non-fatal attack of fever. It was subsequently immune, and showed no reaction when inoculated with virus three months later.

May 8th, 1929.—Rhesus No. 206, inoculated subcutaneously with 1 c.cm. citrated blood of three immune monkeys, VII 9, VII 12, and VII 16. Thirty-six days later it was also inoculated subcutaneously with 0.05 gram of infected liver and spleen of Monkey 210, and died of typical yellow fever after seven days.

In these experiments it will be noticed that in one case (No. 205) some degree of protection may have persisted for thirty-six days, but in the other (No. 206) the immunity had completely disappeared after the same interval. It is evident, therefore, that convalescent serum is of little value for general prophylactic use "unless followed by a dose of active virus" (Hindle, 1929, p. 420).

On the other hand, the inoculation of a mixture of virus and immune serum seems to produce a more lasting immunity, as shown in the following experiments:

January 12th, 1929.—Rhesus No. 155, inoculated subcutaneously with 3 c.cm. of a mixture of human immune blood with 0.1 gram of infected liver. The monkey showed no febrile reaction during the following ten days, while a control animal inoculated with 3 c.cm. of a mixture of normal human blood with 0.1 gram of the same infected liver died of yellow fever six days later. Rhesus No. 155 was inoculated with large doses of virus on April 29th, 1929, and again on September 13th, 1929, but showed no fever or any other signs of infection.

November 3rd, 1928.—Rhesus No. 117, inoculated subcutaneously with a mixture of 5 c.cm. of human immune serum and 0.1 gram of infected liver. The mixture was allowed to stand fifteen minutes at room temperature before being inoculated. The monkey showed no signs of fever—either after this inoculation, or after four subsequent inoculations of large doses of virus (on two occasions as much as 3 grams of infected liver or spleen)—on November 14th, November 25th, and December 30th, 1928, and January 7th, 1929, respectively.

January 21st, 1930.—Rhesus No. 306, inoculated subcutaneously with a mixture of 4 c.cm. citrated blood of a patient who had had an attack of yellow fever twenty-four years previously, together with 0.05 gram of infected liver and 0.5 c.cm. of infected blood. This monkey showed no signs of fever, either after this inoculation or after a subsequent intraperitoneal inoculation of 1 c.cm. infected blood on March 6th, 1930.

March 14th, 1930.—Rhesus No. 316, inoculated intraperitoneally with 5 c.cm. of a mixture of 10 c.cm. hyperimmune monkey serum with 1 gram of infected liver. The mixture was left at room temperature for eighteen hours, and then 5 c.cm. were inoculated into the monkey. The animal showed no reaction after this inoculation, and on April 23rd, 1930, was again inoculated with 1 c.cm. of virulent blood without showing any fever.

In this experiment the immune serum had had no action upon the virus *in vitro*, for 5 c.cm. of the mixture was centrifuged after it had been standing for eighteen hours, and the sediment was washed three times in a mixture of normal saline and ascitic fluid to remove the immune serum. The washed sediment was then inoculated into a monkey (No. 317), which died six days later of typical yellow fever.

It is unnecessary to multiply these examples, which are supported by the independent investigations of many observers. The evidence proves conclusively that the simultaneous injection of immune serum and virus in monkeys produces no obvious ill effects, and, moreover, is followed by a lasting immunity, in marked contrast to the comparatively short duration of the passive immunity produced by the inoculation of immune serum alone.

DISCUSSION

The use of virus and immune serum for immunization against virus diseases has many analogies with the use of a mixture of toxin and antitoxin in immunization against diphtheria. That such a toxin-antitoxin mixture is slowly dissociated was shown by Arrhenius and Madsen (1902), who found that free toxin was liberated from the mixture so gradually, and in such small amounts, that immune bodies were produced in the absence of disease symptoms. Glenny and Pope (1925) have also pointed out that diphtheria toxoid, when injected subcutaneously, will immunize rabbits, but may fail when given intravenously. If, however, the toxoid be partially neutralized by antitoxin, rabbits can be immunized by the intravenous route. This is apparently due to the fact that there is too rapid an elimination after intravenous injection, while the presence of antitoxin in the mixture may delay absorption or elimination. Glenny (1925) therefore concluded that the efficiency of toxin-antitoxin mixtures depends on the slow dissociation of the toxin from the antitoxin, so that the animal injected is constantly stimulated. Now Todd (1928), in the case of fowl pest, and Andrewes (1928), in the case of vaccinia, have shown that dilution of an inactive virus-immune-serum mixture renders the mixture active. The analogy with toxin-antitoxin mixture is obvious. It seems probable, therefore, that a virus-immune-serum mixture, when injected into an animal, gives off virus very slowly, with the result that the active virus is insufficient to give rise to symptoms of disease, but sufficient to produce active immunization.

In the case of vaccinia, the use of a mixture of immune serum and virus would seem to have advantages over the method of vaccination now generally employed, provided that the relationship between the titre of the immune serum and the virus is correctly adjusted.

The fact that a virus-immune-serum mixture has given satisfactory results in two virus diseases so dissimilar as vaccinia and yellow fever suggests that this method may have a very general application in other diseases due to ultra-microscopic viruses.

CONCLUSIONS

Experiments are recorded showing that immunization against vaccinia and yellow fever may be obtained by the injection of a mixture of immune serum and living virus, without giving rise to any general or local reaction.

A REVIEW OF SEX CHARACTERS

WITH SPECIAL REFERENCE TO THE ADRENAL CORTEX

BY

L. R. BROSTER, O.B.E., D.M., M.Ch., F.R.C.S.

ASSISTANT SURGEON, CHARING CROSS HOSPITAL

Science, so far, has been unable to explain what determines sex in animals. Among mammals, with rare exceptions, the sex once acquired is definite and unchangeable, but this stability of the sexes steadily declines as we descend the evolutionary scale. In man we have come to regard the differentiation of the sexes so much an accepted and universal feature of nature that any deviation from this rule at once excites our curiosity. There are cases, however, in which characters common to both sexes have, from time to time, been observed, and it has fallen to my lot as a surgeon to study several cases of women in whom male secondary sexual characters have appeared. This has led me to consider the biological factors concerned, which are presented in this review. By the study of the abnormal we may hope to obtain a better understanding of the normal; and it is for this reason that these cases can make their contribution to our knowledge of sex physiology.

HISTORICAL

In Greek and Roman mythology we read of transformations, both fantastic and picturesque. Sir John Bland-Sutton, in his *Story of a Surgeon*, quotes the following:

"We learn from Ovid, the master of romance and vivid fancy, that Tiresias in his youth interfered with two engendering snakes, and was in consequence turned into a girl. Seven years later, he saw the same pair of snakes again copulating, and separated them with a stick. He was again turned into a man, and became the most celebrated philosopher in Thebes."

In Greek mythology we learn the story of Hermaphroditus, son of Hermes and Aphrodite, who was worshipped as a divinity He had inherited the beauty of both his parents, and thus excited the love of the nymph of the fountain of Salmacis. She tried in vain to win his affections, and as he was one day bathing in the fountain, embraced him, praying to the gods that she should ever be united to him. The gods granted her request, and the bodies of the youth and nymph became joined together, retaining, however, the characteristics of each sex. The figures of Hermaphroditus, half man and half woman, are common in ancient art. This double sex is also attributed to Dionysus and Priapus, embodying in one being the two principles of generation and conception. Dionysus, the young, beautiful, but effeminate god of wine, is described as having a manly form, but approaches the female in softness and roundness.

Sex abnormalities have not failed to attract attention in the sphere of art. M. Achard and M. Thiers record a picture by Ribera of Madeline Ventura, who, bearded at the age of 52, is suckling an infant. In the National Museum at Munich there is a statue in wood of the bearded St Madeline.

The primitive instinct is one of antipathy towards the abnormal Among animals their presence in a herd is not tolerated; it is not unusual to see them feeding at a distance, and they are often attacked and killed. This same antipathy has been shown by man. Crew quotes the case of a cock which, in 1474, was sentenced and burned at the stake in Basel for the heinous and unnatural crime of laying an egg. The executioner, a man with an inquiring type of mind, after fulfilling his office, discovered three more eggs inside. Apparently the same fate befell the sexually abnormal up to 1730. Our attitude has changed since then.

SEXUAL EVOLUTION

In the vertebrate kingdom there are present in each sex, rudiments of the accessory sexual parts of the opposite sex. There are, however, exceptions to this rule. Some individuals combine not only the bodily characters, but also the generative cells of both sexes, and are spoken of as true hermaphrodites. Others, again, with the generative cells of one sex combine the bodily characters of both. No hard-and-fast line can be drawn between the two groups. True hermaphroditism is rare in man, but more common in animals. In pigs, for example, the numbers have been estimated at 1 in every 80,000. Pseudo-hermaphroditism is common in man, and in Warsaw the ratio was 30 to every 800,000 of the population.

In the case of animals and plants with separate sexes, it is obvious that the two elements must always unite for each birth. In true hermaphrodites it is not obvious why they should unite; nevertheless, they either occasionally or habitually do so, for the reproduction of their kind. All vertebrate animals, all insects, and some other large groups of animals pair for each birth. Many hermaphrodite animals do not habitually pair. The vast majority of plants are hermaphrodite. In plants and aquatic hermaphrodites cross-fertilization can be explained by such agencies as winds and insects on the one hand, and of currents on the other. Apparently no land animal is capable of self-fertilization. It is a curious anomaly that in plants some species of the same family are hermaphrodite and others unisexual, yet the difference between them is very small. Hence it appears that, with plants and animals, intercrossing between distinct individuals is almost a universal law of nature. Hermaphroditism may occur in varying degrees in one organism. It may be demonstrable in early life (tadpole) and disappear in adult life as maleness or femaleness predominates, or it may be normal in the adult. Other animals are bisexual; they produce ova at one time and spermatozoa at another. Certain facts suggest that hermaphroditism is a primitive condition, and that the unisexual condition is a secondary differentiation. Yet other facts, where cross-fertilization may be difficult, suggest that the bisexual condition may have arisen as a secondary adaptation.

Another less understood variant in the modes of reproduction is that of parthenogenesis, in which ova produced by the female develop without being fertilized by the male element. This obtains among rotifers and small crustaceans, where the males in some cases have never been found, or are absent for a season. In bees the males may be absent for the summer, or be artificially segregated for years, without affecting the rapid succession of sterile female generations, and the production of drones in the beehive from eggs which have never been fertilized.

Reproduction in the elementary forms of life is by simple cell division. Thus the amoeba splits to form two complete individuals. For all its simplicity, we see its analogy in the highest forms of reproduction, the same division of the fertilized ovum into two cells, each of which may ultimately develop into separate individuals—the so-called uni-ovular twins In the metazoa the same primitive form of asexual reproduction obtains In sponges, groups or clumps of cells sequester off to form new individuals, and if a sponge is cut into pieces these may regenerate the whole. In the higher forms of life this attribute of regeneration remains the sole legacy of the reproductive cells. Volvox, on the borderline between the protozoa and metazoa, presents several peculiar biological phenomena. The adults are balls of cells. In such a ball reproductive units are sent adrift and divide to form new individuals At other times some of

the cells develop into ova and others into spermatozoa. The large cells are fertilized by the small. We may find volvox balls in which only ova are being made, and others with only spermatozoa. Here we have an organism illustrating the differentiation between somatic and reproductive cells, and occurring in asexual, hermaphrodite, and unisexual phases. The analogy between the higher and lower forms of life can be pushed even further. For, in the protozoa, processes corresponding to fertilization are of general occurrence. Periodically, conjugation takes place in which two individuals unite temporarily or permanently. This is an incipient sexual process—the fertilization of an ovum by a spermatozoön.

SEXUAL CHARACTERS

Only when one set of sexual glands (ovary or testis) predominates is it possible to determine the sex of the individual. These are called the primary sexual characters. Associated with this predominance is the development of the correlated sexual organs; and sexual maturity is declared by the acquisition of secondary sexual characters, which are liable to much variation. When the sex glands are completely absent or experimentally removed, as in castrates, the secondary sexual characters shift towards the neuter or intersexual type, and not to the opposite sex. The alternation of maleness and femaleness in the same individual occurs both naturally and experimentally. Sir John Bland-Sutton gives a most vivid description of this sex reversal in the Mexican sword tail:

"It is a pretty fish, almost transparent and about three inches long. In sword tails the sexes are distinct. In the male the anal fin is represented as a pair of claspers, and the lower part of the tail is elongated, and in shape like a sword. The female has a tail of the usual shape among carp—she produces viviparously. It happens not infrequently that after producing fry two or three times, she changes her sex completely. The anal fin becomes claspers, and the lower part of the tail elongates into a sword, as in the male. Indeed the female becomes male, not only in the assumption of male livery, but sheds milt. The change is correlated with the acquisition of functional testes."

Similar changes of sex have been described in fowls.

Another curious biological phenomenon is presented by the so-called freemartin, the female twins of cattle, who not uncommonly exhibit sexual abnormalities. They are sterile, resemble castrates, and have their internal genitalia undeveloped. In twins of different sexes the female is usually abnormal. It has been found that there exist connecting blood vessels between the foetuses and a fusion of the chorions. It has been suggested that the female undergoes masculinization under the influence of the male sexual hormone entering the blood of the female. Where no such fusion of blood vessels obtains, the females are normal.

Secondary Sexual Characters

The variety and intensity of secondary sexual characters has been one of the most conspicuous features in evolution. The male differs primarily in his increased power of locomotion, his special prehensile organs, his greater size, strength, endurance, and pugnacity, and in his special weapons of offence and defence; in birds, by his gorgeous plumage, decorative ornaments, his engaging antics, and his enchanting song. The females are naturally endowed with organs of nourishment and protection for the young. Darwin attributed the greater decorativeness of the males to the sexual selection exerted by the females. The handsomest and most vigorous males succeed in their courtship better than their rivals, and are more successful in begetting a large number of offspring.

The theory of sexual selection is dependent upon the laws of inheritance, the transmission and development of characters. The equal transmission of characters to both sexes is the commonest form of inheritance. But characters are commonly transferred to that sex in which they first appear. Now, secondary sexual characters are transmitted by both sexes, though developed in one. Occasionally characters proper to the male appear in the female, when she grows old or becomes diseased—for example, in the common hen. The first development of characters in the female and transference to the male is less commonly observed. Reversion of characters, which may have been transmitted through two or three generations or many generations, may appear under certain unknown favourable circumstances.

We do not know why certain characters should be inherited by both sexes, and other characters by one alone—namely, by that sex in which the character first appeared; but it seems in a general way that variations which originate late in life tend to be developed in the same sex alone, while variations which first appear early in life in either sex tend to develop in both sexes. In a few cases it must be assumed that there is an embryonic difference in the sexes to account for some characters which are seen only in one sex. For instance, haemophilia is transmitted from the parent male through the daughters, who remain unaffected, to their sons. The same obtains in some forms of colour-blindness. It is probable that the parent transmits characters of the asexual type which are capable of reacting to the male and female influence of a given species.

Hair, which may be considered a secondary sexual character, holds an anomalous position. It seems probable that man is descended from some hairy progenitor, yet its loss must have been an inconvenience to primitive man. The commencement of denudation is seen on the under surface of the female anthropoid ape. As women are less hairy than men, females apparently first had their bodies denuded of hair, possibly as a sexual attraction, and transmitted this character equally to both sexes. On the other hand, our male ape-like progenitors acquired beards as a sexual ornament, and transmitted them to their male offspring.

DEVELOPMENT OF SUPRARENAL GLAND

Suprarenal tissue, comparatively speaking, is of recent acquisition to the animal kingdom, and the history of its development is marked by definite and gradual progress. Appearing first in fish, it is present in all higher animals, increasing in importance so as to become essential to life. Bilateral adrenalectomy in man is followed by death. Associated with this increase in functional importance, we find a corresponding and interesting change in the development process. In its primitive form its origin is single and very intimately connected with the reproductive glands; later, this portion commences an association with the cells of the sympathetic system, of quite a different origin. The completed organ therefore is of dual origin. The suprarenal glands were first described by Eustache during the Renaissance. The term "suprarenal capsule" is really a misnomer, for it was originally thought that the glands were hollow, until Meckel in 1806 pointed out that they were solid, and named them adrenals. Pettit's researches first showed that in mammals and other vertebrates these glands lie not only along the upper poles of the kidneys, which is their common position, but also along the inferior vena cava, the renal veins, and along the large trunks of the abdomen; and that their structure and location varies in different animals.

In man the suprarenal glands lie across the upper poles of the kidneys, and consist of a central portion, or medulla, surrounded by the cortex. The medulla is composed of the chromaffin cells, which have a special affinity for, and stain yellow with, chromate salts. The

cells of the cortex are more compact in texture, being differentiated into three zones. They have an abundance of fatty granules, and readily stain with osmic acid. To differentiate these cell types, Balfour in 1878 chose the name of interrenal organ for the lipoid-containing cortex, as opposed to the suprarenal, comprising those cell groups which simulate the adrenal medulla.

Development of the Interrenal or Cortex

The interrenal or cortex is derived from the mesothelium of the Wolffian ridge from which the gonads arise, and extends from the pronephros to the cloaca. About the fourth week a series of buds, resembling a chain or rosary, can be distinguished from these coelomic cells at the root of the mesentery. These buds sequester off, and coalesce, forming a ridge, which projects into the colon between the mesonephros and root of mesentery. In the 6 mm. embryo it appears as cell groups just caudal to the pronephros, and in the 9 mm. embryo it is a dense cluster of cells medial to the Wolffian body; in the 12.5 to 14 mm. embryo there are signs of capsule formation, and the cells are well vascularized, becoming arranged in layers.

Development of Medulla

The cells of the medulla have the same origin as the nervous cells of the abdominal sympathetic ganglia. They proliferate and separate off to form an association with the cells of the cortex.

Fusion of Elements

The changes associated with the formation of the adrenal gland in man are peculiar in that the same process has not been observed even in the higher apes. In the third month the sympathetic formative cells (sympathogonia) commence to grow into the cortex to form the medulla. This invagination proceeds along the central fold which contains the main vein in such a way that the greatest surface of contact obtains between cortex and medulla, until the medulla is entirely closed by the cortex. Just before birth the maximum stage of development is reached, in which the adrenal is about one-third the size of the kidney, whereas in the adult the ratio is only 1:28. No other organ shows such marked changes in its subsequent history. In the newborn (till the end of the second month) the cortex gradually becomes reduced by a process of absorption. Fatty infiltration in the form of coarse fat drops appears in the hyperaemic cortical cells, for the most part in the middle and inner zones, and these cells are gradually destroyed. The external layer, whose cells contain only fine granules of fat, survives to regenerate the cortex, which is completed, with adult form, about the second year; and the organ then grows *pari passu* with the rest of the body. The onset of puberty heralds a new and active growth of the cortex. At this stage it is twice as heavy as the testis, whereas later it is one-half or one-third this weight. The three zones become more sharply defined. The outer, germinal or glomerular, zone forms the two inner zones, and the cells contain fine fat droplets, but are poor in lipoids. The fascicular zone is rich in lipoids, and the cells contain large fat droplets. The reticular zone cells contain small fat droplets, but are laden with pigment, which increases with age. In woman the glomerular layer is increased in comparison with man; it enlarges at each period and with pregnancy, and these differences are akin to those found in the pituitary. Between the fourth and fifth decades, the cortex is at the zenith of its development. From this time on there is a gradual senile involution, more marked in the glomerular layer; while the fascicular layer increases in volume. These changes are greater in males than in females.

During the course of this development two facts may be stressed. In the adrenal of the newborn, during the stage of fatty disintegration of the hyperaemic cells, haemorrhage may readily occur—a point which should be borne in mind in applying violent methods of resuscitation. In cases of foetal anencephaly it has been noticed that the adrenals are unusually small. Microscopically it has been found, not that the glands have failed to develop, but that the post-partum changes described have occurred during foetal life, and that the adult gland has already been established. Since the brain is so largely composed of those complex lipoid cells upon whose production the adrenal may have some influence, it is possible that the failure of cerebral development in these cases is due to a disturbance of lipoid metabolism induced by the premature maturity of the adrenal glands.

COMPARATIVE ANATOMY

The story of the adrenals would not be complete without some reference to their comparative anatomy. In fishes—the elasmobranchs, the teleosteans, and selachians, groups comprising the sharks and rays—the two cell systems are separate and distinct. Medullary tissue is found scattered along the parietal vessels and sympathetic chain, whereas the cortex exists as a separate structure, the so-called interrenal body. Coexisting with this interrenal body we find a marked development of the sexual system. The pelvic fins have their hinder ends modified in the male to form special copulatory organs, the myxipterygia or claspers. In the teleosteans specialized corpuscles are found on the dorsal and ventral surfaces, and even in the substance of the kidneys. These were first described by Stannius, who considered that they corresponded to the interrenals of the selachians. In amphibians the adrenals are placed loosely along the ventral surface of the kidneys, and stand out as yellow flecks against the dark brown kidney. In some classes of amphibians they appear as a large number of yellow nodules placed in series along the kidney. In this group the first advance of the two cell systems towards each other is observed, and islands of medulla cells are scattered about in the substance of the cortex. In reptiles the morphological characters of the adrenals present more intimate association with the genital glands than with the kidneys, with a large preponderance of cortical tissue. In some species we find an even closer association between the two cell systems, the medulla lying dorsally and the cortex ventrally. In other species there is a tendency for the medulla to be situated peripherally around the cortex. Chromaffin substance is also found in the sympathetic ganglia, and along the inferior vena cava and renal veins. In birds the adrenals, two yellow-coloured masses on either side of the vena cava, lie in the neighbourhood of the upper poles of the kidneys, the left just posterior to the ovary. Microscopically the two cell systems are mixed together in groups, with a preponderance of cortical tissue.

ACCESSORY ADRENALS

From the nature of the developmental process it is to be expected that accessory or misplaced adrenal tissue should be of common occurrence. Chromaffin cells are usually found in relation to the sympathetic ganglia, and may exist as accessory structures. These have been described from time to time in the region of the root of the superior mesenteric artery, and along the abdominal veins. Similarly, any failure on the part of the interrenal buds to coalesce would give rise to accessory interrenal bodies. Such bodies are usually referred to as accessory adrenals, but from their nature it would be wiser to differentiate them as accessory interrenal bodies. True accessory adrenals composed of cortex and medulla are rare, whereas accessory interrenals are very common, and are most often

found near the adrenals, about the gonads, in the broad ligament, along the spermatic veins and inguinal canal, and in the epididymis.

PATHOLOGY

In comparison with tumours of the medulla, those of the cortex are more homogeneous in type, yet their differentiation has been the source of fierce debate among pathologists. Nor has the matter yet reached finality. The contest has raged round the subject of the so-called hypernephroma. True adrenal hypernephromata arise from the cortex of the adrenal or accessory interadrenals. Their entity was challenged by the discovery, nearly forty years ago, by Grawitz, of tumours closely resembling the cortex in structure, but arising outside the sphere of the adrenals. These hypernephromata, or what should be termed renal hypernephromata, have been most commonly found in the kidneys, and have been recorded in places where accessory adrenals occur—namely, the retroperitoneal tissues, pancreas, broad ligament, and even in the ovary and testes. This led Grawitz to attribute their origin to adrenal rests. The position of the Grawitzian hypernephroma has been strongly attacked by Stoerk, Glynn, and others, and many have relegated them, more especially the papillary forms, to the category of renal adenocarcinomata. The classification of these tumours has been complicated by the fact that it has been found that many tumours of the ovary which have been described as ovarian hypernephromata are really not hypernephromata at all, but lutein tumours. Glynn, in an admirable paper, has done much to clear up the subject, and considers the acceptance of Grawitz tumours has been too complete.

In view of the difficulty and unsettled pathology, it appears reasonable to adopt for the present an arbitrary clinical classification of hypernephromata into those which are associated with virilism and those which are not:

A. *Tumours of the Adrenal Cortex*

1. Hyperplasia. Nodular and diffuse, or bilateral.
2. Hyperplasia. Unilateral.
3. Adenoma.
4. Hypernephroma of the adrenal cortex.
5. Carcinoma.

These are invariably associated with virilism.

B. *Tumours Resembling the Adrenal Cortex*

1. Renal hypernephroma.
2. Ovarian hypernephroma.
3. Large lutein tumours.

These are not associated with virilism.

The hyperplasias are rare, and we find gradations between these and the adenomata. They are commonly found in infancy and old age, and when bilateral they give rise to pseudo-hermaphroditism (feminine). Unilateral hyperplasia is found after puberty in the second and third decades, and is associated with marked virilism. This type receives scant reference in the literature, is probably the commonest and most important of all the groups, and will be more fully described later. The adenomata may be single or multiple. They are circumscribed, rarely encapsulated, may be large, with a tendency to haemorrhage and softening, and often become malignant. Carcinoma occurs frequently. The atypical cases are difficult to dissociate from sarcoma, and the ratio of carcinoma to sarcoma is 10:3. They form soft yellow tumours, which grow rapidly, and are prone to necrosis and cystic change. Bony metastases are infrequent, and their progress is rapid and fatal.

Hypernephroma

In view of the variability displayed by this tumour, it may be well to emphasize some of the characters observed in the different groups.

True Adrenal Hypernephroma.—Macroscopically, this tumour resembles the more common renal hypernephroma, with a tendency to haemorrhage and necrosis, but it is less yellow and has not the same tendency to form cysts. Microscopically, the resemblance to the normal adrenal cortex is slight; the cells and their nuclei are distinguished by the greater variation in their size and shape, by the absence of the characteristic clear and very vacuolated cytoplasm, and apparently by the complete absence of well-formed gland lumina. The histological appearances are a small index to malignancy, and there is no real difference whether the tumours are from the young or old, male or female, with or without sex changes. Virilism with amenorrhoea is invariably present.

Renal Hypernephroma or Grawitz Tumour.—Macroscopically, there are large, yellow, fatty, vascular, circumscribed tumours, prone to haemorrhage and cyst formation. There is usually a central fibrous area surrounded by a more cellular portion. They arise within the kidney capsule, displacing the renal substance, and may extend along the renal vein. Microscopically, there is a striking resemblance to one of the zones of the adrenal cortex. The cells are arranged either in small circular groups separated by strands of connective tissue (zona glomerulosa), or the elongated cords of zona fasciculata may predominate. The cytoplasm is slightly granular, numerous lipoid and glycogen granules yielding a foamy texture. Lumina are present. Virilism is absent. These tumours become highly malignant, are rapidly fatal, and very commonly disseminate in bone.

Ovarian Hypernephroma.—Macroscopically, these are solid yellow tumours with haemorrhagic and necrotic areas; sometimes there are a few degenerate cysts of yellow colour, containing fat. Microscopically, there is a general resemblance of groups of clear or very vacuolated cells lying in a capillary stroma very much like the zona fasciculata. The cytoplasm is clear and extensively vacuolated, and the presence of glycogen and lumina is well marked. There is a close resemblance to the structure of the adrenal cortex and to the renal hypernephroma, and consequently these tumours have been thought to be of adrenal origin.

Lutein Tumours

Macroscopically, these tumours apparently arise in the ovary. They are large, generally about the size of a foetal head, usually malignant, yellow, haemorrhagic, and with necrotic areas and cysts. Microscopically, there is a resemblance of clear or very vacuolated cells in a capillary stroma to the zona fasciculata. The cytoplasm is clear and vacuolated, glycogen and lumina are present, but to a lesser degree than in ovarian hypernephroma. The cellular hyperplasia of the lutein layer has been mistaken for ovarian hypernephroma, and, both macroscopically and microscopically, there is no essential difference between these tumours. Glynn, in an exhaustive examination of these tumours, comes to the conclusion that only in one case (*Bovin's*) of a hypernephroma in the broad ligament associated with virilism was there evidence to show that the tumour was a true adrenal hypernephroma of an accessory suprarenal. Considering that accessory suprarenals are common in the broad ligament, few *hypernephromas* have been recorded there; and there is no proved case of cortical rests either in the ovary or in the testis. This case is probably the only true adrenal hypernephroma which has been described as occurring in the female pelvis.

Virilism, either complete or partial, has been described in association with cystic or dermoid tumours or semi-solid tumours of the ovary, but there is no evidence that the adrenals in the cases were examined.

CLINICAL SYNDROME

It has long been known that the ductless glands exert a powerful influence on our health and physical development. The facts at our disposal show that they function as a whole in a concerted and orderly manner. We have been able to assign certain clinical syndromes to pathological processes in the majority of them, and we ascribe their influence to an internal secretion, which acts in virtue of its over-secretion, under-secretion, or disordered secretion, via the blood stream. Any dysfunction of one is apt to unsettle the balance between the others, and it is the interpretation and correlation of this intricate system of interaction to which so much study is now being devoted.

There is abundant evidence to show that certain of these glands are intimately concerned with general bodily growth, and of such organs as the sexual in particular; that the continued secretion of these glands is necessary for the maintenance of this growth at a normal level; and that growth will be inhibited when the flow ceases or diminishes. The most striking change associated with the adrenal group is the accentuation of the male secondary sexual characters, and these may be most aptly described under the heading of "Virilism," rather than the more cumbersome appellations in literature, such as the "Adreno-genital syndrome." As long ago as 1756 W. Cook established the association of hypertrichosis and adiposity with adrenal tumour. The association of secondary sexual changes with adrenal tumour was known to John Hunter, and, though cases were sporadically recorded, it was not till 1905 that the true correlation was confidently emphasized in a publication by Bulloch and Sequeira. Unfortunately, many of the earlier case reports are unsatisfactory in that the clinical manifestations were ascribed to various pathological processes, and the real causative factor was either overlooked or not examined.

The clinical changes which constitute virilism may be grouped as follows:

Changes Involving the Sexual Organs.—In women, atrophy of the uterus, changes in the ovary, under-development of the labia, and overgrowth of the clitoris. In males, precocious sexual and somatic development—for example, a boy aged 6 may possess the sexual and somatic development of a full-grown man.

Changes Affecting Bodily Contour.—In women, narrowing of the hips, broadening of the shoulders, atrophy of the mammae. Either marked muscular development or the deposition of fat.

Disturbances in the Sexual Function.—Irregular menstruation, amenorrhoea, miscarriages, and failure to bear children.

Alteration in the Secondary Sexual Characters.—Hirsutism of the male type, either a beard and moustache or mutton-chop whiskers. The hair on the body is of the male type, curly and crisp, and well marked on the limbs. On the body the pubic hair extends up to the umbilicus and may be well developed on the chest, shoulders, and small of the back. Development of the larynx in women is accompanied by cracking of the voice with a concomitant bass voice. Linea distensae or striae may be found on the flanks and thighs, and are probably a result of increased adiposity.

Perversion and Change.—This is difficult to ascertain, but Holmes quotes a case in which there was lack of modesty and loss of erotic feelings.

The type of virilism depends on the time of onset and the duration of the symptoms, and may be conveniently classified as follows:

1. *Congenital Type.*—Probably all cases of feminine pseudo-hermaphroditism belong to this group, in which the sexual glands are female and the secondary sexual characters are male. Serious misapprehension as to the sex of the individual may arise in later years. These cases are associated with bilateral hyperplasia or occasionally an enlarged accessory adrenal.

2. *Puberty Type.*—This is a common variety, and changes commence at puberty or soon after. It is entirely confined to young women, who develop either the obese or muscular type of virilism, in which hirsutism and menstrual disturbances predominate. Whether this type is a direct result of the increased activity of the adrenals which takes place at puberty, or at birth, we do not know; but we do know that it is associated with adenoma and unilateral hyperplasia; and it may even occur with adrenal tumour.

3. *Adult Type.*—In adult women, including multipara, the reversion to the male type is less marked; hirsutism followed by amenorrhoea, involution of the breasts, atrophy of the uterus and ovaries, obesity; miscarriages may supervene. The pathology is identical with Group 2.

4. *Obstetrical Type.*—After the menopause, hypertrichosis followed by obesity, psychical disturbances, and asthenia supervene. The loss of hair follows the masculine rule, and it is not uncommon to see the recession of the hair, and even temporal baldness in elderly women. This group, like the congenital, is accompanied by bilateral adrenal hyperplasia. There is now evidence to show that, after surgical removal of adrenal tumours in suitable cases, women have shown a most striking reversion to their own type, in regard both to psychical and to secondary sexual characters.

PATHOGENY

On the analogy of the behaviour of other endocrine glands it is probable that the adrenal cortex elaborates an internal secretion, which passes into the blood stream and, when present in excess, is capable of producing the changes already referred to. How this hormone acts is subject to much speculation. Swale and Vincent maintain that it acts directly on the reproductive system. It is also suggested that it is an adjuvant to the testicular hormone in the amplification of the secondary male sexual characters, and is not antagonized by the ovary; or that it acts reflexly on the sex characters via the pituitary, pineal, ovary, and testes. Blanchard contends that it is the interstitial cells of the gonads which are directly responsible for virilism. Krabbe offers an ingenious explanation by asserting that the ovary is originally bisexual, the cortex being male and the medulla female, and that cortical hypernephromata are tumours caused by riotous growth of misplaced sex elements in the adrenal. This view has been criticized by Gordon Holmes, Kemp, and others, who doubt such chance inclusions, and point out that these tumours, associated with sex changes, approach in microscopical appearance the normal structure of the adrenal cortex. Keith believes that it is through the adrenal cortex that the gonads produce the changes associated with puberty. Lipschutz maintains that the adrenals exercise a masculinizing effect on the sex glands. In support of this is our knowledge that pineal and pituitary tumours may be associated with the same changes. Crosbie and Smith assert that the sex characters are regulated by the interstitial cells of the gonads, and that this function may be assumed by the adrenal cortex.

So far there is no evidence that hyperplasia of the cortex can be produced experimentally.

It is difficult to come to any definite conclusion as to what type of hormone is elaborated, but it is probably a hypersecretion, upsetting the endocrine balance in which the gonads are concerned. It is essentially a masculinizing effect, heightened in the presence of the male sex gland, but apparently not much modified or altered in the presence of the ovary. Nor are we able to say precisely which cell type is concerned with the elaboration of this hormone. The available evidence points to the cells of the adrenal cortex and sustentacular cells of the testis. The latter are the more potent in producing the finer points of male characterization. In the adrenal cortex it is probable that the cells of the outer zone are most directly responsible. This is not surprising in view of their common ancestry.

PHYSIOLOGY

Since the discovery of the blood-pressure-raising effect of extracts of the adrenal medulla in 1894 by Sir E. Sharpey-Schafer, a great deal of attention has been devoted to its physiology, but no such far-reaching effects have been accorded to the cortex. Apart from the production of virilism, the cortex is credited with a close association with lipoid metabolism, being the storage organ for cholesterol fats.

It has been suggested that the cortex forms a precursor to epinephrin, but there is no valid reason to indicate that any mutual co-operation exists between cortex and medulla. There is, however, evidence that the cortex acts as a detoxifying agent. During the acute infections—streptococcal, diphtheria, and scarlet fever—the protoplasm of the cortical cells shows marked vacuolation and loss of lipoids, and it is thought that in this process the cholesterin or cholesterin esters saturate or inactivate poisons or toxins. Yet in starvation the lipoid content of the cells remains unchanged.

Modern Conception of Gonadal Internal Secretions

A vast amount of experimental work has been devoted to the influence of the sexual glands, in an endeavour to explain the problem of the sexes. The bulk of this work emanates from the Continent, and the inquiry has been pursued from two aspects: (1) the grafting of sex glands; (2) the injection of extracts from the sex glands.

It is now accepted that every organism in its earliest development passes through an asexual stage, and that the soma reacts to maleness or femaleness by the specific action of the sexual hormones. This theory is supported by castration experiments in which the animal more or less loses its sex characters and tends to assume an asexual or neuter form. If a gonad is transplanted into a castrated animal of the other sex, the animal reacts to the former—that is, the hormones act as a sex specific. The most successful grafting experiments have been of this nature, for it has been found that there exists a certain antagonism between ovarian and testicular grafts on uncastrated animals, although simultaneous ovarian and testicular graft can produce experimental hermaphroditism, with variations in psychosexual behaviour. In these experiments it has not been possible to discount the interaction of the other endocrine glands. Thus, it has been possible to establish certain facts: (1) Formation and persistence of sex characters depend on sexual glands. (2) The formative and causative influence of the sexual glands do not relate to all sex characters. (3) The formative and causative influence of the sexual glands concern not only the sex characters involved in sex function—that is, genitals, heat, psychosexual behaviour—but characters in special relation to sex function—plumage, etc.

Internal Secretion of the Testis and Ovary

The clinical evidence available with regard to the testis shows that the interstitial cells are a necessary part of the testicular hormone, and there is no proof of an independent hormone elaborated by the cells of Sertoli or the tubules. With regard to the ovary, the position is less clear, and the endocrine function is intimately connected with processes taking place in the follicle. Consequently, all experimental results based on the injection of gonadal extracts have been conflicting and disappointing. This is not surprising considering the compound structure of the sexual glands, and the fact that we cannot control the rhythm of their normal function. Moreover, it has been found that the sexual hormones are not specific for each species. It is not until we can establish the quantitative rate and rhythm of the secretory action of the gland that we can hope for more success from the injection of extracts.

UNDULANT FEVER IN INFANCY

BY

BRUCE WILLIAMSON, M.D.ED., M.R.C.P.LOND.

PHYSICIAN TO THE ROYAL NORTHERN HOSPITAL; ASSISTANT PHYSICIAN TO THE PRINCE OF WALES'S GENERAL HOSPITAL

AND

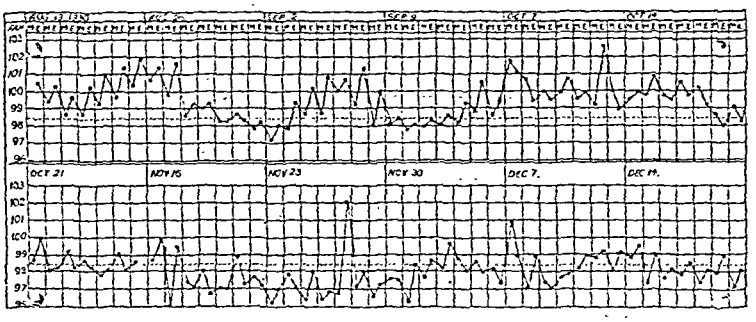
A. J. GIBSON, M.B., B.S.LOND.

HEYWOOD

During recent years sporadic cases of undulant fever have been recorded in these isles from time to time, and it would appear that they constitute only a small percentage of the cases which actually occur. There seems to be no question that the infection is spreading, and that what was formerly known as Mediterranean or Malta fever has been found in practically every country in Europe; it is also widespread throughout the United States. The causal organism, the *Brucella melitensis*, has been found in goats, cattle, horses, pigs, cats, and dogs, and the prevalence of animal infection in this country was shown by routine agglutination tests carried out at the Royal Veterinary College, London, in 1927–28, which returned positive results in 31.8 per cent. of 928 cows and heifers.

Sir W. Dalrymple-Champneys, in his report to the Ministry of Health on undulant fever, makes the statement that children under 5 years are almost exempt, and it is chiefly on this account, and because of our inability to find any previous record of a case in infancy in Britain, that we have made the following communication. As in the majority of cases described in this country, the causal organism was not isolated, but serologically and clinically there is no doubt that the following case was one of undulant fever.

R. H. B., male, aged 20 months, was in excellent health until July 30th, 1930, when a cold in the head developed. Following this there was vague ill-health, with loss of appetite, and the temperature became irregular, with recurrent attacks of pyrexia lasting about ten days, the highest figure being just over 102° F. With the fever there was diarrhœa, followed by constipation during the afebrile periods. Physical examination showed lymphoid hyperplasia in the posterior triangle of the neck, an easily palpable spleen, and definite enlargement of the liver. Despite the fever the patient looked quite fit throughout, and even during the pyrexial attacks was in no degree prostrated.



Three weeks after the onset the blood count was as follows: red cells 5,100,000 per c.mm., white cells 5,000 per c.mm. (small mononuclears 80 per cent., large mononuclears 4.7 per cent., polymorphonuclears 13.6 per cent., eosinophils 0.7 per cent., mast cells 1 per cent.); haemoglobin 60 per cent., and colour index 0.58. A second count, made on October 10th, during a febrile period, showed a rise in white cells to 14,125 per c.mm., 38 per cent. being large mononuclears, 20 per cent. small mononuclears, 11 per cent. hyalines, and 31 per cent. polymorphonuclears. The blood Wassermann reaction was negative, the urine was normal, while the Widal reaction for typhoid and paratyphoid A and B was also negative.

The nature of the infection was disclosed by a positive serum reaction to the *Brucella abortus* (Bang) up to a dilution of 1 in 250.

In investigating the source of infection we found that the father of the patient was a dairy farmer at Brentwood, and he admitted that a somewhat higher percentage of abortion than usual had occurred among his cows. There was no history of ingestion of goat's milk. None of the family had been abroad. Three other cases of unexplained pyrexia in children from the same district were investigated, but in none could a positive serum reaction be obtained. The most recent report records that the patient is now in excellent health.

We are indebted to Dr. T. H. C. Benians and Dr. E. I. Clark for the pathological investigations which led to the diagnosis of the case.

INFECTIONS AND INSULIN ACTION

OBSERVATIONS ON AN UNUSUAL CASE

BY

R. D. LAWRENCE, M.D., M.R.C.P.

AND

R. A. McCANCE, M.D., M.R.C.P.

(From the Diabetic Clinic, King's College Hospital, working for the Medical Research Council.)

Sepsis and febrile infections are well known to antagonize insulin action in diabetics, so that the usual dose of insulin may have to be doubled or trebled. No adequate explanation of this fact has been produced, although two theories have been advanced to account for it:

1. The products of infection themselves destroy or inactivate the insulin in circulation. Such products may be bacterial toxins or more likely enzymes, such as trypsin,[1] [2] produced by leucocytes and pus. It is known that the ferments of pus cells[3] destroy insulin *in vitro*, but this has not been proved to happen *in vivo*. This hypothesis may be called the theory of "chemical inactivation."

2. It has been suggested that the inhibition is due to the stimulation of the adrenal and thyroid glands[4] by infections, and that it is their increased activity which antagonizes insulin action. This suggestion has been supported by some animal experiments, but the evidence is certainly not conclusive. This may be called the theory of "hormonal antagonism."

The case described below is very unusual, and supports the second theory. Increasing sepsis was accompanied by diminished insulin requirements, the diminution coinciding with a failure of the patient's resistance and reaction to the infection.

DESCRIPTION OF THE CASE

A diabetic girl, aged 16, had been treated for two years with insufficient insulin. On admission to King's College Hospital in May, 1930, she was found to require 140 units a day on a diet of 80 grams carbohydrate, 67 grams protein, and 135 grams fat. She was therefore a very severe case, unusually "insulin resistant." She was a careless out-patient, and in August developed a large staphylococcal abscess in the thigh at the site of an insulin injection, a unique occurrence in our experience. This infection increased the insulin requirements for a week after the opening of the abscess. Healing was complete in three weeks, and she left hospital on a dosage of 140 units a day. In December, 1930, she developed a similar abscess in the upper arm, and her insulin requirements became 200 units a day. This was followed in ten days by another abscess near the shoulder-joint, and, in spite of free drainage, a succession of pyaemic abscesses appeared. Pure cultures of *Staphylococcus aureus* were obtained from them, and a positive blood culture in the fourth week. She died in the seventh week. At the post-mortem examination numerous abscesses were found throughout the body, and about 2 pints of pus in the pericardial sac. Until the end her appetite and digestion remained unimpaired, and the total quantity of the diet was kept unchanged. Frequent changes in insulin dosage were required, these being controlled by urine and blood sugar tests.

The pertinent features of her case, the insulin requirements, the average maximum temperature, and the white blood counts, are shown in the accompanying table. The two last are indications of her reaction to the infection. They show a gradual failure from the fourth week onwards; this was in keeping with the clinical appearance.

After the second week the degree of sepsis and the amount of retained pus became progressively greater. The table indicates that her insulin requirements rose from 140 to 200 units at the onset of the infection, and fell progressively to 80 to 90 units as her resistance failed, in spite of an increase of the severity of the sepsis.

	Insulin Units	Temperature	White Blood Count
Before infection	140	98·6°	
1st week	200	102·0°	
2nd week	200	103·0°	
3rd week	200	103.0°	23,000 per c.mm. Polymorphs 95%
4th week	170	102.0	31,000 per c.mm. Polymorphs 96%
5th week	140	101.0°	13,000 per c.mm. Polymorphs 89%
6th week	100	100·5	11,600 per c.mm. Polymorphs 93%
At 6½ weeks	90 80	99·0°	

DISCUSSION

As it is possible to exclude all the other factors which might have reduced her insulin requirements, we are forced to conclude that they depended on her progressive failure to react to her infection. Thus, while it is known that progressive emaciation may improve the diabetic condition, this was absent in her case. It was impossible to weigh her, but there was no visible reduction in her slight obesity, nor was there any failure to eat and absorb the usual total amount of food. Variations in her endogenous insulin production were very improbable, as she had been a very advanced diabetic showing no variation in her insulin requirements for the eight months during which she was under our observation. On the other hand, there was no change in the type of infection and no abatement of its severity as the insulin requirements grew less. The same bacteria, and presumably the same toxins and type of pus, were present in increasing quantities, and she should, if the theory of chemical inactivation be true, have required more insulin in the later weeks.

It seems fair to conclude, therefore, that it was not the sepsis or toxins *per se* which inhibited insulin action in the early stages of this case, but the reaction to them as manifested by a rise of temperature. When the latter failed, the insulin acted better. The febrile reaction seemed the determining factor, and it will be noted that the insulin diminished as soon as the average temperature began to fall, and before any change was seen in the blood count. Further evidence of the importance of a febrile reaction (as distinguished from a non-febrile infection) must have been noticed by insulin workers in comparing the effect of common colds in adults and in young children. The same degree of coryza (as far as we can judge) will cause pyrexia in a child, but not in an adult. The child requires more insulin; the adult does not, as a rule, unless he has a "feverish cold."

The above evidence associates the inhibition of insulin action directly with a febrile reaction, and only indirectly with the sepsis or infection producing the fever. Perhaps the explanation can be carried further, but not with any certainty, as too little is known of the mechanism producing fever. One hypothesis, however, explains the facts we have observed. Cramer[3] advocates the view that a febrile reaction is produced by the stimulation of the adrenals and thyroid by infective agents, and has developed his arguments in a recent book, to which readers are referred. This would afford an adequate explanation of the inhibition of insulin, as it has been proved experimentally that the hormones of these glands, adrenaline and thyroxine, are direct antagonists to insulin. Clinical evidence is also clear on the harmful effect of hyperthyroidism on diabetes, and also of conditions of nervous strain and excitement in which the suprarenal is stated, and may reasonably be presumed, to be overactive. If we grant in this case that the failing febrile reaction was due to an exhaustion of the adrenal-thyroid apparatus, it is easy to understand why the insulin requirements grew less in spite of increasing sepsis.

Unfortunately, even if the above hypothesis be true, it does not suggest any therapeutic measure in infections other than an increase of insulin. We have tried ergotamine,[4] a sympathetic depressant, which in theory should be ideal, and, indeed, in practice augments insulin action, but its toxic properties have shown it to be undesirable.

SUMMARY

An unusual case of septicaemia in a diabetic is reported in which the insulin requirements, after an initial increase, became progressively less as the sepsis grew worse. This reduction coincided with a falling temperature and failure of reactive powers. It is suggested that the inhibition of insulin action by sepsis is not directly due to the sepsis or toxins, but to the accompanying febrile reaction. It is further suggested that this reaction may be due to the increased activity of the adrenal and thyroid glands, recognized antagonists to insulin. If their reaction fails or diminishes, as in this case, then the antagonism to insulin is removed, and the dose required becomes less, in spite of increasing sepsis.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

KERATITIS PUNCTATA SUPERFICIALIS

From the number of cases of keratitis punctata superficialis that one formerly came across it could not, I think, have been termed a common ocular affection, yet the number of cases I saw during the past winter leads me to believe that it is now of much commoner occurrence than might be expected. It is a condition very easily missed, and one not likely to be found unless carefully looked for. Practically all the recent cases have been mistaken for, and treated as, a conjunctivitis. This is owing to the fact that the conjunctiva shows a mild hyperaemia of both its palpebral and conjunctival portions; there is no true discharge, as is present in conjunctivitis, but an excess of tears. The pain is of a gritty, burning nature, and more severe than would be encountered in a conjunctivitis of so mild a degree. There is also considerable photophobia, which is far more pronounced and distressing than in a case of conjunctivitis.

If the cornea is examined with an ordinary light nothing abnormal is seen, but with focal illumination and a magnifying glass, particularly if the pupil is dilated, the surface of the cornea will be seen to be cloudy and scattered over with several minute grey dots, the numbers of which vary considerably. They may be arranged in groups or rows, and are very much more abundant in the centre, the periphery of the cornea being often quite clear. If fluorescein is instilled into the conjunctival sac some of the spots are stained green, but others remain unaffected. An examination with the corneal microscope shows the spots to be of a superficial nature, involving

only the corneal epithelium; they vary in colour from a brilliant white to a dull grey, some being round, others stellate in shape. The remaining corneal epithelium is oedematous. The deeper structures of the eyes are not involved.

If correctly treated, the condition appears to take one of two courses. The ocular irritation and the corneal spots may disappear in a few days, or the irritative symptoms may rapidly pass off, but the corneal spots remain, gradually clearing up over a period of some weeks. In none of the cases that I have seen has there been any permanent impairment of vision.

The condition may attack one or both eyes, and, although it is said to occur most frequently in young people, recent cases would show that its occurrence in middle age is as frequent as at any other time. There is no doubt, I think, that catarrh of the air passages, and particularly the influenzal cold, has a definite bearing on the ocular condition, many patients complaining that they had had a succession of colds, and that during one of these the eyes had become red and irritable. The condition occurs more frequently in women than in men.

As regards treatment, the only real essential is not to employ any irritating drug—such as mercury or zinc—which will probably have been used if the case has been mistaken for conjunctivitis. I have obtained the quickest results with a lotion of normal salt solution, used warm three or four times a day, and in a mild case no other treatment is necessary. Protosil ointment of 5 per cent. strength may be put into the conjunctival sac just before bedtime every night. Heat is beneficial, the best method being to immerse in a bowl of hot water a piece of lint or flannel, wring it out, and apply it to the closed lids, continuing this for ten minutes every three hours. In the more severe cases coloured glasses are both restful and protective. Whether catarrh of the nasal passages is present or not, it is probably beneficial to give some nasal antiseptic. I have employed chloretone inhalant (P. D. and Co.), used with an atomizer.

In conclusion, therefore, in what looks like a case of mild conjunctivitis with marked irritative symptoms, a careful examination of the cornea should be made, and even if, without special instruments available, this appears normal, all irritative treatment should be stopped and a saline lotion substituted, and the progress of the case watched for a week or ten days.

E. R. CHAMBERS, F.R.C.S.ED., D.O.M.S.
Ophthalmic Surgeon, Bristol Royal Infirmary.

ACUTE URETHRITIS IN MUMPS

The following case has several unusual features:

The patient, a middle-aged man, had one son, aged 11, at home from school suffering from a mild attack of mumps. The boy had developed definite parotitis (but no testicular involvement) on March 9th. His case ran a normal mild course.

The family live in comfortable circumstances in the country; the father comes to town daily. He called to see me in London on March 26th, complaining that for a week he had had urethral irritation, some pain, and a free discharge of pus. The patient's circumstances were against a gonococcic infection, and the laboratory report confirmed my own findings, there was a muco-purulent discharge, but no gonococci. Next day I received a telephone message that my patient was feverish and in bed. On examination I found his temperature was 100.8°; slight pain in left parotid. Twenty-four hours later the parotid was swollen to an enormous size, and the urethral discharge still continued, but it appeared to be lessening and the inflammation and redness at the mouth of the urethra was not so marked. On April 1st the left testicle rapidly swelled, the patient's morning temperature being 103°, and at 11 p.m. 104.8°; there was slight delirium.

Progress Notes

April 2nd. Temperature, morning 103°, evening 103.2°; slightly easier, but vomited twice; some epigastric pain and distension (? acute pancreatitis).

April 3rd. Temperature, morning 101.4°; general condition much better, but testicle very large and tender.

April 4th. Temperature 98.6°; very much easier.

April 8th. Temperature normal; testicle down to half; no urethral discharge.

April 12th. Testicle very nearly normal; patient getting downstairs to-day.

All through the illness there was evidence of a very severe infection, with delirium and some collapse on the fifth and sixth days of the fever. The pancreas may have been involved.

It is of some interest that a lady friend, aged 25, who was living in the house, developed mumps on March 30th—a mild case, but with considerable pelvic pain.

London, E.C.1. ARTHUR SPENCE, M.B., Ch.B.

Reports of Societies

EPIDEMIOLOGY OF VENEREAL DISEASES

At the meeting of the Section of Epidemiology and State Medicine of the Royal Society of Medicine on April 24th, with Professor MAJOR GREENWOOD in the chair, Colonel L. W. HARRISON read a paper on the epidemiology of venereal diseases.

Colonel Harrison, after remarking on the notorious fallacy concerning the statistics of venereal diseases, explained that he had constructed various tables and graphs mainly from a census carried out in Switzerland in 1920–21, in which an effort was made to obtain particulars from practitioners and institutions, from a German census in 1927, from a number of official Scandinavian figures, from various one-day censuses in the United States, and from such British figures emanating from the treatment centres as were available. He compared the incidence of venereal diseases in large towns and cities with their incidence in smaller places, and showed how great were the differences in this respect. In Norway, in 1924, for example, the rate per 10,000 was 30.7, but in Oslo it was 134; in Sweden, for the whole country, it was 18.7, but for Stockholm 99.2; in Germany, in 1927, the rate was 58, but in Berlin it was 136, and in Kiel 164. In the Swiss census the towns of more than 50,000 inhabitants showed three times the average for the whole country, and the villages only one-fourth of the average. Turning to age and sex incidence, Colonel Harrison said that it appeared from the various figures that the age of greatest incidence was 20 to 24, with the peak occurring earlier in females than in males. Recently, in connexion with a League of Nations inquiry, he had sent to Geneva approximately 3,000 records of early cases of syphilis, giving the date of infection, and analysis of these figures showed that on an average the males in this country acquired syphilis at a later age than in Germany or France. The rates for the men in the Services (except for gonorrhoea in the Navy) compared favourably with those for civilians of the same age group in Germany. Higher rates of syphilis in female children up to 10 years suggested that congenital syphilis was commoner in females than in males; which, if true, was a curious fact, seeing that in the periods of sexual activity females tended to react less to the virus than did males. An alternative possibility was that more female syphilitics survived after birth. Another fact to be noted was that there was a much lower ratio of females to males in respect of gonorrhoea than in respect of syphilis, suggesting that

there was a large amount of hidden gonorrhoea in women. For example, in Greater New York (1928) the ratio of males to females in early syphilis was 1.87 to 1, but in gonorrhoea it was 4.41 to 1. In Oslo (1926) the ratio for syphilis was 1.9 in males to 1 in females, but for gonorrhoea 3.5 to 1. In the treatment centres of England and Wales (1929) the corresponding figures were 1.8 to 1 for syphilis, and 4 to 1 for gonorrhoea. Figures for the German census (1927) showed that for the age group 20 to 29 the rate of primary syphilis in males and in females according to the stage when first treated was 15.8 and 3.8; but in the case of secondary syphilis the sex position was reversed, the rate for males being 9.8 and for females 13.9, indicating the tendency of males to seek early treatment and of females to delay. There was little or no evidence of the diminution in incidence of gonorrhoea. Syphilis increased in most countries during the war, then declined rapidly until 1924, after which it declined more slowly, remained stationary, or actually increased. Soft chancre had declined very greatly, and there was strong evidence that in Western Europe a large proportion of cases now came from abroad. He compared three English centres dealing practically only with seamen, at which the percentage of soft chancre was found to be 5.7, with four inland centres, at which the percentage was 0.3. Colonel Harrison discussed the influences affecting changes in the incidence of venereal diseases. The effect of salvarsan on syphilis might be neutralized by increased promiscuity and under-treatment. The view of Haustein was that the incidence of venereal diseases waxed and waned with economic prosperity, that of von During and others that it followed epidemic curves like other infectious diseases. Colonel Harrison was himself inclined to Haustein's view. He produced the figures for the incidence of syphilis in the British forces stationed at home per 1,000 of strength. In 1921 the respective figures for the Navy, Army, and Air Force were 8.1, 9.8, and 4.1. In the Army and Air Force there had been a progressive diminution, but in the Navy, after reaching 3.1 in 1925 and 1926, and 2.3 in 1927, the figure rose to 5.2 in 1928 and 7.9 in 1929. The corresponding figures for 1929 in the Army and Air Force were 2.1 and 0.8. He also made an attempt to estimate the incidence of fresh syphilis in this country about 1900 by taking the death rates for general paralysis of the insane from 1914 to 1918, but he admitted that this was of very doubtful value on account of the varying views as to the incidence of general paralysis in syphilis. He described a Swiss method of calculating the probable number of persons in a community who had been infected with syphilis; this resulted in a figure of 0.8 to 1 per cent. for that country. Haustein's calculations of percentages in some large European towns showed rates which were much higher than seemed to obtain in London and Glasgow.

Dr. J. D. ROLLESTON said that he had kept a record at a London fever hospital of the number of cases admitted as suffering from one of the acute notifiable infectious diseases and in which the final diagnosis was syphilis. The number was quite small, ranging from 0 in 1923 to 7 in 1928. Dr. DALY (London County Council) asked whether sufficient was known about the contagion of syphilis for anything to be laid down as to its constancy. In other infectious diseases infectivity waxed and waned, and it might be that the spirochaete at one period was more virulent than at another. There was a possible reason for the increase in the number of cases of syphilis in the past year or so. In the old days, when treatment was incomplete, he presumed that the syphilitic person acquired a certain immunity; but now, as the result of clearing up entirely the syphilitic virus in these patients, a larger number of people who had been syphilized five or ten years ago, having since been exposed again, were presenting themselves as fresh cases of infection.

Dr. E. F. HODSON said that the figures for general paralysis of the insane gave no indication of the prevalence of syphilitic infection in a community. Out of one hundred cases of syphilis, general paralysis might not be the late manifestation in any one of them. In the Tropics he had seen many cases of syphilis and never a case of general paralysis. This as a late manifestation occurred most frequently among intellectual persons, while locomotor ataxia was apt to develop among those who did hard manual labour, and syphilitic aneurysm among those whose occupation called for spasmodic effort. Sir GEORGE BUCHANAN said that more exact information might be expected as the result of the elaborate case-treatment papers which were being collected from the clinics in different parts of Europe and America. These would furnish, he hoped, some quite new sources of information of international significance about the results of different kinds of treatment with arsenical compounds. Dr. CARSWATH suggested that it would be interesting to work out the correlation between incidence of syphilis and unemployment, and Dr. H. S. STANNUS asked whether any figures were available as to the relative proportion of infections from professional prostitutes and from amateurs. Professor MAJOR GREENWOOD pointed out certain difficulties in any estimation of incidence based on deaths from general paralysis of the insane, and Colonel HARRISON, in reply, said that he had endeavoured to work out, but with very little success so far, the incidence of syphilis in various classes of the community. He thought there was general agreement that there was now far more sexual promiscuity than formerly, and that the amateur played a larger part in infection than the prostitute.

RIEDEL'S DISEASE

At a meeting of the Liverpool Medical Institution on April 9th, with the president, Professor W. BLAIR BELL, in the chair, Mr. C. O. DAVIES read a paper on Riedel's disease.

After a brief survey of the available literature on the subject, he gave the clinical history and pathological features of a case of Riedel's thyroiditis in a married woman, aged 26. Discussing the difficulties of differential diagnosis from malignant disease of the thyroid, he said that Riedel's goitre usually occurred in a previously healthy gland, did not form a bulky tumour, and had a smooth surface. The pressure symptoms were severe for the size of the goitre. Carcinoma most frequently appeared in a gland previously pathological, and formed a large tumour, which was uneven and nodular on the surface. Mr. Davies drew special attention to the fact that adhesions of the goitre to surrounding tissues made thyroidectomy a very difficult procedure. Lantern slides demonstrating the transition from an early stage, in which the gland was chiefly occupied by a round-celled infiltration, to the formation of fibrous tissue were shown.

In the discussion which followed, the PRESIDENT asked Mr. Davies how the toxic symptoms, such as tachycardia, were caused, when the lesion invariably destroyed the thyroid tissue; even though the disease were limited to a portion of the gland one would not expect hyperthyroidism. He also wondered what was the condition of the parathyroids in this form of thyroiditis. Had they been examined? He thought one or more must sometimes have been removed along with the capsule, to which the adherence of adjacent structures had been emphasized by Mr. Davies as being an important surgical difficulty. Dr. HOWEL EVANS said that the etiology of Riedel's struma was quite unknown. The condition was a rare one—the

other specimens described were certainly the only ones seen in the Thompson Yates Laboratory during the past twelve years.

DYSTOCIA AND ENLARGED BLADDER

Dr. M. A. DOBBIN CRAWFORD and Dr. T. N. JEFFCOATE reported a case of dilatation of the urinary tract in a foetus, causing dystocia. A woman, aged 35, having had six normal confinements, went into labour at the thirty-fourth week of her seventh pregnancy. She was sent to hospital as a case of obstructed labour, the child born as far as its chest, and dead. Dystocia in this case was due to an enlarged foetal bladder, which required puncture before delivery could be completed. The foetal bladder, dilated and hypertrophied, completely filled the abdomen; there was an associated condition of bilateral hydronephrosis. The interesting features of the case were that it occurred in a female foetus, there was no evidence of any urethral obstruction, while the genitalia and all other parts of the body were normally developed. A suggested cause was that it was due to an abnormality in the neuro-muscular mechanism. The question whether the foetus normally secreted urine whilst *in utero* was discussed. The view was put forward that it was pathological for the foetal kidneys to function before parturition.

The PRESIDENT said that he did not think it was necessary to lay much stress on non-obstruction of the urethra in some of these cases, for one so often saw post-operative paresis of the bladder wall with considerable distension and even hypertrophy, without urethral obstruction or damage. He thought the fact that the kidneys might have secreted earlier and more freely than normal was probably a factor of importance. They did not know when normal renal activity and urination first occurred; many children, without the stress of labour, passed urine immediately after delivery by Caesarean section.

TREATMENT OF NERVOUS EXHAUSTION

At a meeting of the Chelsea Clinical Society on April 21st, with Dr. F. J. MCCANN, the president, in the chair, Sir E. FARQUHAR BUZZARD opened a discussion on the treatment of nervous exhaustion.

Sir Farquhar Buzzard said that "nervous exhaustion" was a diagnosis which he practically never made, and a condition, therefore, which he hardly knew how to treat. When he said to himself that nervous exhaustion was another type of neurasthenia he was no better off, because "neurasthenia" was a term employed to cover a variety of morbid states clinically resembling each other, but therapeutically calling for different methods of attack. The patient who came up with a diagnosis of nervous exhaustion was generally found to be free from any signs of organic disease of the nervous system or of serious disease of any other organ which would account for his state of ill-health. His symptoms were that he was easily tired, mentally and physically, lacked concentration, was unable to make decisions, his memory was not what it used to be, he was not taking the same interest in his pursuits, he was depressed, perhaps agitated, irritable, over-reactive to noise, and sometimes restless, complaining of headache, indigestion, constipation, palpitation, with vague pains in various parts of the body. A statement that the patient was suffering from overwork would no doubt be acceptable to him and his family, but, fortunately or unfortunately, fatigue from excessive mental strain was a physiological rather than a pathological condition, and one from which recovery was rapidly made under the influence of rest. Experiment had shown that the fatigue produced by mental work was evanescent. Overwork must be dismissed as a frequent agent in the production of nervous exhaustion. More often the cause might be described as preoccupation of a personal or emotional character, amounting, in fact, to an anxiety neurosis. It was not unfashionable to lay the blame for nervous exhaustion on a chronic toxaemia, but he was not impressed by the results of treatment based on such a diagnosis, although, of course, it was important to deal with any such sources of ill-health if they existed, whether their share in bringing about nervous exhaustion was primary or not. But the large majority of patients who sought advice for symptoms characteristic of nervous exhaustion belonged to one of two categories: the anxiety-neurotic and the manic-depressive. It was only by discriminating between these two types that a correct method of treatment could be adopted. The chief obstacle to the recognition of a manic-depressive psychosis was its unfortunate name, with its asylum associations, so that the majority of such cases were labelled neurasthenia. He preferred the term "autonomous depression" when comparing this condition with the depression of the anxiety state. This disorder, as met with in everyday practice, presented every degree of severity, from the condition of a normal happy individual who was subject to occasional moodiness to that of the individual who was certified as suffering from mania or melancholia. Success in making the distinction between the anxiety state and autonomous depression could be achieved only by a careful exploration of the history and symptoms, including the history of suicide or alcoholism in the family. He was convinced that a large number of chronic alcoholics were essentially manic-depressive, and were alcoholic because they were manic-depressive. One distinction between the two states was that the anxiety-neurotic would come to the physician willingly and with hope, whereas the psychotic had to be brought against his will, and stated that he was not ill, but had come only to please his wife. The neurotic ascribed his illness to other things, to bad luck or to malign people, while the psychotic placed the blame upon himself. The neurotic was more apt to seek distraction and to benefit by it temporarily; but the psychotic avoided distraction and social intercourse. The depression in the case of the psychotic was always at its worst in the morning; sleep might not be disturbed, but waking was horrible. The typical anxiety-neurotic slept badly. Treatment must depend upon the cause. If the exhaustion were really caused by overwork and were in an uncomplicated form it would certainly yield to rest and change. The exhaustion due to toxaemia clearly called for the removal of the septic focus if it could be found. Nervous exhaustion due to anxiety needed active treatment, by which he meant some form of psychotherapy, requiring, in the first instance, a careful and sometimes prolonged mental investigation. If the anxiety could not be resolved, then some form of compensation, readjustment, or sublimation must be aimed at. He was not sure that psycho-analysis, using the term in its highly specialized sense as implying that it could be practised by only a few people, was either necessary or always beneficial, but some analysis of the mental contents should be made in order to determine what was important and what was merely secondary. The person suffering from autonomous depression needed assiduous care; mental investigation into his case, so necessary in the case of the neurotic, must be avoided lest it drive him to desperation. A willing ear, ready to hear the same old miserable story day after day, unremitting sympathy and encouragement, and a mild degree of exhortation—such must be the doctor's contribution to this patient's recovery. There was no condition in which a doctor's frequent visits were so necessary and so seemingly unproductive, and it was always wise to see that the work and responsibility were divided between two or more individuals.

In the discussion which followed, Dr. TRAVERS SMITH thought that the range of possible causes mentioned by Sir Farquhar Buzzard might be widened to include the possibility of latent tuberculosis, malignant disease, anaemia, myocardial insufficiency, low blood pressure, and arterio-sclerosis. In addition to anxiety and manic-depressive states there were others to be considered, one of them being obsessional neurosis, and, again, nervous exhaustion might be a matter of hysteria pure and simple, without anxiety. It might also arise as a result of self-accusation due to previous masturbation, perhaps dating back to a distant period. Dr. P. SEYMOUR-PRICE asked whether it was not possible for nervous exhaustion to be a pure and simple exhaustion of nerve energy, a case of a really tired-out nervous system, which with rest and treatment might get perfectly well. Was it any wonder that the business man of to-day, with things as they were on the Stock Exchange or in the City, or the woman of to-day, with things as they were in domestic service, became utterly exhaused? These people should not be labelled psychotic or anxiety-neurotic; they were just ordinary people very short of nerve energy. Dr. J. CAMPBELL MCCLURE recalled a remark by Pierre Janet that a man could exhaust himself as much by arguing with himself as by addressing a large public meeting. Overwork plus worry certainly did exhaust nervous energy. Dr. E. C. YOUNG referred to the association of many of these cases with gastric disorder. He thought that in nearly all it would be found that they were of the atonic type. He quite agreed that if one could gain the patient's confidence, attend to his digestion, put him to bed, and give him perhaps something to make him sleep for a time, great good could be done. Dr. C. E. SUNDELL drew attention to the many cases of children who suffered from nervous exhaustion. It was out of the question to regard these children as manic-depressive or anxiety-neurotics, and they were too young to be masturbators. Here was a simple example of a nervous system which for some reason or other had got tired. He took the view that there was a very definite entity in the shape of a nervous system which was unable to stand up to the strain of physical and mental life. A man's nervous energy depended upon "the type of copper wire used in his electrical system." Dr. E. P. FURBER, who declared himself a sceptic in regard to psycho-analysis, gave some account of cases with emotional difficulties.

The PRESIDENT said that a true type of nervous exhaustion was seen as a result of ordinary labour. There were women who were completely exhausted through reproduction, and in their case one could exclude every possible cause of local infection. Such cases used to be very difficult to treat, but undoubtedly glandular therapy had afforded great assistance. A second type of case showing nervous exhaustion was often seen in women who devoted themselves to looking after elderly mothers, who became increasingly difficult as the years went on. Some of these women suffered from a type of nervous exhaustion extremely difficult to treat.

Sir FARQUHAR BUZZARD, in reply, said that he believed any general practitioner in his ordinary practice might see fifty manic-depressive cases in the course of a year, although he might not recognize them as such or call them by that name. That was his apology for stressing that aspect in his remarks. Cases of suicide were mainly at one period of manic-depressive psychosis, but doctors failed to recognize the condition. The anxiety-neurotic patient was a possible suicide, and the psychotic patient was. He cases of syphilis had not laid much stress on pure exhaus- when treatment was tion, because such patients did not syphilitic person acquired with a little rest and bromide as the result of clearing up agreed with Dr. Sundell as to the these patients, a larger number of cases of nervous exhaustion in children.

Reviews

BACKACHE

More than two years ago, in a leading article under this title, reviewing the discussion held in the Orthopaedic Section of the British Medical Association at the Cardiff Meeting in July, 1928, we expressed a hope that the papers then read might "attract the attention of all British surgeons to the importance of the problem of the causation and cure of backache, and of the need for very careful and thorough investigation." In his book on *Backache*,[1] recently published, Dr. JAMES MENNELL shows us that for a number of years he has been working at this subject, and that, as a result of his investigations into the vast amount of clinical material which has come into his hands, he has arrived at certain very definite conclusions as to the causes and cure of backache. It appears that the teaching of Goldthwait of Boston first stimulated Dr. Mennell's interest and started him on a thorough inquiry into American work in the study and treatment of posture and back troubles, for the subject has aroused infinitely more attention in the United States than in this country.

The conclusions to which Dr. Mennell has come as to the causes of backache, the frequency of various phenomena, and their relief by manipulation and other non-incisive proceedings, may not be readily accepted by practitioners in Europe, but they urgently claim the attention of all surgeons and, we may add, of physicians, for Dr. Mennell describes himself as an orthopaedic physician and not a surgeon. Backache is not a rare symptom only interesting to the specialist and pathologist. It is probably one of the troubles most widely complained of in all ranks of life, and may be of all grades of severity, from a mere worry to a disabling and excruciating agony. Bonesetters, and of late years osteopaths and chiropractors, have had the credit of curing some of these cases; but, if Dr. Mennell's conclusions are accepted and his methods put in practice by others with such success as he himself has been able to secure, he may claim to have taken the wind out of the sails of the unqualified practitioner. In one respect at least Dr. Mennell differs from the majority of American writers on the subject. He attaches little or no importance to constipation or intestinal delay and stasis as a cause, whereas American orthopaedic surgeons of such distinction as R. B. Osgood attribute a very important role to these conditions in causing, for example, symptoms resembling those of lesion of the sacro-iliac joint.

Surgery in general, and orthopaedic surgery in particular, is an art based on science, and science, we are told, is measurement; but unfortunately in the study of backache much is not demonstrable to the eye or to the touch of the doubting Thomases of our profession. Sensitive deposits in the soft parts are not generally dissected out and laid in sections on the stages of microscopes, nor has the frequency of cases of locking of vertebrae or ribs been so clearly exposed to demonstration as congenital dislocation of the hip and other luxations. Torsion strain of the sacro-iliac joint is not so obvious as a sprained ankle. These are some of the difficulties which beset the way of an orthopaedic physician who sets out, as Dr. Mennell has done, to bring into the light of day the obscure conditions concerned in the cure of pains in the back. We here use the word "cure" advisedly in its older sense, not necessarily of *redintegratio ad integrum*, but in that of the sixteenth century, in which

[1] *Backache*. By James Mennell, M.D., B.C.Cantab. Illustrated by Margaret Morris. London: J. and A. Churchill. 1931. (Pp. viii + 199; 48 figures. 10s. 6d.)

it meant treatment as well. His book should find a large public, but we would warn the reader that it is not a statistical work. In it will not be found tables showing the sex or age incidence of backache or of the ratio between cases treated of each morbid condition and cases cured or relieved. But there will be found information frankly and clearly set out, with the help of which the reader may test for himself the validity of the author's claims. We hope that the medical profession will eagerly avail itself of the opportunity. Many conditions met with in medicine and surgery are relieved or cured under treatment which we can only characterize as empirical, and in which the question, "How does it work?" is unanswerable. In such cases simple pragmatism seems to be the only reasonable attitude to adopt, and the substitution of the question, "Does it work?" Dr. Mennell and many surgeons in America would answer this affirmatively, and his book should enable many more in this country to do likewise.

The illustrations by Miss Margaret Morris are remarkable. Their artistic merits deserve the praise bestowed on them by Dr. Mennell, but we question the propriety of the representation of the manipulator as a nude figure. It was no doubt advisable for clearness' sake to get rid of the patient's garments, but why strip the physician to the skin? It is true that the illustrations are mere outlines of nude figures, but Miss Morris's art is such that they convey to the reader impressions that are more realistic than many more finished drawings.

DISEASES OF THE BLOOD

This well-known work, Blood Diseases and Diagnosis,[1] by OTTO NAEGELI, has been out of print for some years, and the appearance of a new version is not unexpected. Though now expanded to over 600 pages a large portion of the text remains verbatim as in previous editions. Many chapters, however, notably that dealing with pernicious anaemia, have been rewritten and brought into line with modern research.

The earlier sections are concerned somewhat meagrely with methods, special stress being placed on the importance of physico-chemical tests, such as sedimentation rates, viscometry, estimations of albumin, globulin, fibrinogen, etc.; many of these tests are rarely employed in clinical laboratories, and in the present state of knowledge their significance is chiefly of academic value. In enumerating red cells it is advised to wait twenty minutes or longer after filling the counting chamber before making a count; this may be safe for normal blood, but for anaemias it has been shown to cause great error from the effect of contact haemolysis. In a long and interesting discussion on the vexed question of the origin of the different varieties of white cells, Professor Naegeli makes out a good case for "dualismus," the separation of myeloid and lymphatic cell systems, a scheme which is now widely accepted. His argument is supported by descriptions and illustrations of the mother cells of these two classes, myeloblast and lymphoblast; nevertheless, it must be admitted that, in practice, to recognize and distinguish these cells must always be difficult and often impossible. In the consideration of Arneth's nuclear lobulation it is allowed that a "shift to the left" is important for the clinical recognition of infections, but the interpretation of the shift as the appearance of young cells in response to a greater need for leucocytes is not accepted. Professor Naegeli believes that the estimation of the age of a neutrophil leucocyte should be guided by the staining reaction showing changes in the structure of the nucleus—the ratio of basi- and oxy-chromatin—rather than by the degree of nuclear segmentation, which is often difficult to determine and may be artefact and result from injury in preparation. There is no reason to suppose that a cell with a five-segmented nucleus is older than one with three segments. The polysegmented nuclei of the neutrophil leucocytes met with in pernicious anaemia are regarded as characteristic of the disease.

The presence of megalocytes in the blood is universally accepted as the chief histological evidence in the diagnosis of pernicious anaemia. To most haematologists a "megalocyte" is an abnormally large red cell, and the presence and degree of megalocytosis is estimated by some direct or indirect method of cell diameter measurement. Professor Naegeli recognizes two types of large red cells: the "megalocyte," derived from megaloblast and met with in the blood of pernicious anaemia, and the "macrocyte," which is found in other forms of anaemia and belongs philogenetically to the normoblast series. He does not regard the size of red cell diameters as necessary evidence for the presence of megalocytes. To distinguish true megalocytes from macrocytes is not easy, and the author admits that young forms of megalocytes and macrocytes cannot be distinguished. We consider the recognition of these two varieties of "big cells" of great importance, in view of the occurrence of "megalocytic" anaemias wrongly diagnosed as pernicious anaemia.

Space prevents further discussion of the many interesting questions suggested in this book. As an encyclopaedia of haematology it will be welcomed alike by haematologists and clinical workers. The enormous literature of this subject has undoubtedly overwhelmed the author; had he omitted from his text some of the older references, now only of historical interest, he could have given more serious consideration to many recent and valuable papers which unfortunately he has buried in bibliographical catalogues, where they cannot be recognized or used by readers. The habit of publishing catalogues of references without context-indicating letters or numbers is undesirable.

DIABETIC SURGERY

Nowadays diabetic patients are no longer considered unsuitable subjects for surgical operations. Insulin has changed all that, and surgeons will be well advised to read with attention MCKITTRICK and ROOT'S *Diabetic Surgery*.[2] Formerly coma was the chief cause of death among diabetics, but with insulin at hand a death from coma is an unnecessary death, and surgical complaints (infections for the most part) head the list of causes of death in diabetes. Acute infections and arterio-sclerosis rank high among these causes, and the authors warn surgeons that they must expect widespread arterio-sclerosis in the elderly diabetic. But the influence of arterio-sclerosis need not be regarded with despair; it appears to be on the increase at present, because diabetics are living long enough to develop it. In future insulin and diets containing less fat and more carbohydrate may check this tendency to arterio-sclerosis. Another valuable piece of advice is that the surgeon should always take pre-operative glycosuria as evidence of diabetes until the contrary is proved by blood sugar analysis. High blood sugars without glycosuria are mentioned as a source of danger and difficulty. Pre-operative diets are dealt with, and it is suggested that no deliberate operation should be

[1] *Blutkrankheiten und Blutdiagnostik.* Von Dr. med. Otto Naegeli, LL.D. H.C. Fünfte vollkommen neubearbeitete und erweiterte Auflage. Berlin: J. Springer. 1931. (Pp. xvii + 704; 104 figures. R.M. 86.)

[2] *Diabetic Surgery.* By Leland S. McKittrick, M.D., F.A.C.S., and Howard F. Root, M.D. London: Baillière, Tindall and Cox. (Pp. 259; 79 figures, 2 plates. 21s. net.)

undertaken until the patient is taking approximately one gram of protein and twenty to twenty-five calories per kilogram of body weight. In no circumstances at all should a diabetic starve in preparation for an operation, for with insulin any diabetic can take a large amount of carbohydrate before operation. A further useful hint is that there is great danger in giving large doses of insulin to render the urine sugar-free in a few hours before emergency operations. Similarly, rapid reduction of the dose of insulin may be required to avert severe hypoglycaemia during convalescence, because rapid gains in carbohydrate tolerance may occur. The effects of anaesthesia and the choice of anaesthetics are judiciously considered, while the surgical conditions to which diabetics are peculiarly liable are discussed most carefully, together with all the minutiae of surgical technique which the authors' experience has taught them to insist upon. One point emerges very clearly: the surgeon who operates on a diabetic subject will need in future to be a thoroughly sound physician. But there is nothing new in that—all the really great surgeons of the past were sound physicians too. The book is well printed and splendidly illustrated.

B.C.G. VACCINATION AGAINST TUBERCULOSIS

The literature on the B.C.G. strain has become so great and so diffuse that Dr. ROLAND CHAUSSINAND has rendered valuable service in bringing out his book on vaccination against tuberculosis by B.C.G.[4] In it he summarizes the most important observations, and discusses critically some of the results that have been obtained. The first part of the book is devoted to vaccination of animals, both in the laboratory and in the field, and to the innocuousness of the B.C.G. strain. In the second part the technique and the practice of vaccination in the human subject are considered, together with a summary of the results reported from the different countries. It is interesting to note that Dr. Chaussinand criticizes the oral route of administering the vaccine. Though undoubtedly the easiest method in general practice, it has the disadvantage of leading to only a very slow development of allergy, so that the infants have often to be restored to a tuberculous environment before the tuberculin reaction has become positive. This disadvantage, he maintains, is largely avoided by the use of the subcutaneous or intramuscular method of administration. The third part consists of a bibliography, of ample proportions but by no means complete, of the papers published on the subject of B.C.G. This will be found useful, particularly by those who have had neither the time nor the opportunity to follow the individual contributions to this much-debated subject.

HEALTH IN THE TROPICS

Since the days, not long past, when Manson instituted the teaching of tropical medicine and laid the foundation of preventive medicine in tropical countries, advances in knowledge have been so rapid and additions to that knowledge so numerous that it is a difficult matter for the medical officer carrying on his duties in our colonies and elsewhere to keep up to date. The appearance of Dr. BALFOUR KIRK'S *Public Health Practice in the Tropics*[5] will be welcomed by members of the medical and sanitary services abroad as a concise, accurate, and up-to-date account of the problems with which they are called upon to deal. The preface and quite a considerable part of the book might be read with advantage also by administrators and others whose work is less directly bound up with problems of preventive medicine. The first chapter deals with climate, dietaries, and clothing, and follows generally accepted ideas, though (as the author shows) it is far from certain that those ideas are always based on sound physiological principles. Consideration is then given to the application of the principles of maternity and child welfare, as we know them in this country, to tropical communities. There follow chapters dealing in turn with all the endemic and epidemic diseases commonly met with in tropical countries, including small-pox, tuberculosis, and venereal diseases, but excluding amoebic dysentery, the typhus group, dengue and phlebotomus fever, dermal leishmaniasis, and pellagra. Each disease is viewed from the standpoint of the hygienist, and methods of collecting local data are explained. In Part II, under the heading of sanitation, are considered: housing; town planning; schools; milk and water supplies; markets, etc.; latrines; collection and disposal of excreta and refuse; and disinfection. The whole forms a volume of convenient size, well printed and well indexed.

Hints on Equipment and Health for Intending Residents in the Tropics,[6] by the same author, has now reached a second edition, and is a well-known little handbook for the sportsman, prospector, missionary, and explorer, and the many others whose work takes them into tropical countries. Most of the advice offered is such as has been found by common experience to be good. On minor points there may always be difference of opinion. Dr. Kirk recommends "for afternoon functions of a more or less formal and festive nature . . . a grey morning suit. This with a grey top-hat is a much more comfortable attire than the conventional black, which, however, you will also require." How many of those who go to the Tropics require either? Puttees are advocated, but many who have tried it prefer a light, easy-fitting canvas legging with simple fastening. The advice in regard to body clothing would not appear to rest on a sound basis. There are reasons for believing that a single garment (a shirt) made of thin porous honeycomb cotton material may be the most satisfactory. The author advises a sweater to be put on after hard exercise: a change into dry clothing is preferable. Again, *pace* Dr. Kirk, a cold tub in the morning has an excellent tonic effect: the daily cold bath got a bad name because it is harmful to those suffering from chronic malaria or from bowel and liver affections. The value of this most useful book would be enhanced if some of these debatable questions were dealt with in more detail.

ADVICE TO PARENTS

In *The Modern Parent*[7] Dr. GARRY CLEVELAND MYERS sets out the many ways in which even the most conscientious of his readers may err in handling a child; but he is sympathetically aware of the difficulties, and does not regard parents who fail repeatedly in their task as either knaves or fools. He describes the discourtesy, nagging, and emotional stimulation to which children are often subjected, illustrating these offences by concrete examples, and suggesting the remedies. In the course of the book he covers a wide field, but is careful to warn parents against the mental indigestion which might prompt them to attempt a sudden revolution in their dealings with their children. More is to be gained, he believes, by concentrating on one difficulty at a time, and surmounting it before

attacking the others. Moreover, his advice is extremely encouraging to those whose past failures may lead them into despondency. The book is decorated with flowers of colloquial American speech, of which "fresh and chipper" is among the more attractive.

NOTES ON BOOKS

Mr. REYNOLD H. BOYD has compiled a very useful little book entitled, *Diet and Care of the Surgical Case*.[1] It contains a number of practical hints in the preparation of patients for nearly every type of operation, and in the treatment to be followed subsequently, special points being indicated whereby the maximum degree of post-operative comfort may be ensured. Directions are given for the making of foods, enemata, applications, and so on. The volume is of a handy size, so that it will slip easily into the coat pocket. It should prove particularly useful to house-surgeons in the early days of their apprenticeship.

The twentieth edition of *Minor Surgery and Bandaging*[2] has been brought out under the aegis of Mr. GWYNNE WILLIAMS, the chapter on anaesthetics having been revised by Dr. Dudley Buxton and Dr. H. N. Webber. Since it first appeared in 1861 new editions of this book have been published with almost monotonous regularity at intervals of about three years. It would be idle to do more than call attention to another birthday in the case of a book which has met with such constant approval by so many generations of students. Changes, of course, have been made here and there in the text, but they are all concerned with methods which have been practically tested and have passed into the ordinary routine of house-surgeons—for instance, the injection treatment of varicose veins. We can see no reason why new editions of this handbook should not go on appearing *in saecula saeculorum*.

A French translation of Professor A. CASTIGLIONI'S admirable History of Medicine,[10] which was reviewed in the *Journal* of February 18th, 1928 (p. 266), has recently been made by Mlle J. BERTRAND and Professor F. GIDON of Caen University. Its appearance will be welcomed, not only in France, but also in this country and the United States, where French scholars far outnumber those able to read Italian. The work has been revised by the author, who has brought the text and bibliographies up to date.

A further account has been published of the work of the Institute of Anatomy of the Imperial University of Kyoto, edited by Professor SEIGO FUNAOKA. It takes the form of an investigation into the physiology of the circulation of lymph, and the first part, which has now been issued, deals with the radiography of the lymphatic ducts.[11]

A high standard of knowledge is required from those who aspire to enter the nursing profession, not only in the practical details of their duties in the wards or the sick-room, but in general anatomy, physiology, medicine, and surgery. The fourth edition of a book which was designed to cover the whole field of a nurse's theoretical training has recently appeared—a *Text-Book for Nurses*,[12] by Mr. HEY GROVES and the late Dr. J. M. FORTESCUE-BRICKDALE. The medical section in the new edition has been revised by Dr. J. A. Nixon. The names alone of the authors should be a sufficient guarantee of the excellence of the fare provided, and that it should reach a fourth edition proves with what acceptance it has been welcomed by those for whom it is intended. The authors have endeavoured to cover all the ground laid down by the General Nursing Council in its syllabus, and they have certainly compressed a vast amount of knowledge within a remarkably small compass.

Recent Advances in Analytical Chemistry[13] is a digest of newly announced principles and methods of analysis, which are discussed in greater detail than is usual in published abstracts. This volume, which deals only with the organic section, covers an extensive range of matter, and includes the subjects of pure science as well as those of technical importance. Many of the descriptions contain a sufficiency of detail to enable the reader to dispense with reference to the original publications, but in all cases complete bibliographical references are given. The book is well prepared and well indexed.

PREPARATIONS AND APPLIANCES

VITAMIN A (B.D.H.)

Vitamin A (British Drug Houses Ltd.) is a preparation of this vitamin in highly concentrated form made from fresh mammalian liver. The preparation is standardized biologically upon rats, and chemically by the antimony trichloride test. The latter test gives a value of 900 blue units. (Good cod-liver oils give values of from 10 to 20 blue units.) The preparation is put up in capsules containing 3 minims, and the figures mentioned above indicate that each capsule has a vitamin A content at least equal to that of a dessertspoonful of cod-liver oil. This preparation contains no vitamin D, and provides a means for giving vitamin A alone in massive doses. Recent researches indicate the great importance of vitamin A in raising resistance to infection, and the appearance of this preparation will facilitate clinical examination of the therapeutic properties of vitamin A as distinct from vitamin D.

"WELLCOME" DIPHTHERIA PROPHYLACTIC

Diphtheria prophylactic (T.A.F., or toxoid-antitoxin flocculés) is a new preparation issued by Messrs. Burroughs Wellcome and Co. The immunization of young children against diphtheria is a prophylactic measure the value of which has been firmly established during the past decade. The standard methods have been the injection of either a toxoid-antitoxin mixture, or the toxoid alone after this has been converted into a harmless form by formalin and heat. The only objection to this procedure is that three injections, at intervals of a week, are needed, and that reactions are apt to follow. The advantage of the T.A.F. preparation is that it is less likely to cause reactions; moreover, it is believed to be of somewhat higher immunizing efficiency than the older preparations, and experience may show that two injections are enough.

LACTOGEN

Lactogen is a new infants' food manufactured by the Nestlé and Anglo-Swiss Condensed Milk Company. It is a dried cow's milk to which cream and lactose have been added. The proportions of fats and carbohydrates approximate to those occurring in breast milk, and the excess of proteins is less than that which occurs in untreated cow's milk. The makers claim that the dried milk contains a good supply of vitamins A, D, and B. The preparation has enjoyed a large sale in many oversea markets for several years, and is now being introduced to this country.

ANOTAL

Anotal is a combination of phenyl cinchoninic acid and ethyl urethane; it has the title of phenyl cinchonoyl urethane and the formula $C_6H_5C_9H_5N.CO.NH.COOC_2H_5$. It is sold by Messrs. Napp Ltd. Phenyl cinchoninic acid, or cincophen, is a drug whose popularity in the treatment of rheumatic pains has steadily increased in recent years. The advantage of the new combination is that it causes no gastric disturbance. The makers claim also that it has no adverse effect on the heart, and that, according to previous experience, there is no reason to believe that it causes yellow atrophy of the liver.

COELIAC DISEASE

Coeliac disease, though not one of the commonest of the chronic digestive disorders of childhood, is perhaps at the present time the most interesting of them all. On its practical side it is capable of producing such a degree of ill-health and misery in the individual child that its recognition by the practitioner is of prime importance, and clinicians may justly claim that by their improved methods of diagnosis and treatment the hard lot of the coeliac patient has been considerably mitigated. On its theoretical side the difficulty in tracing the essential cause of the disorder presents a fascinating problem, which has attracted many investigators in recent years. In this matter workers in our own country have been much to the fore; and this is as it should be, for the disorder was first described here by Samuel Gee in 1888, and more closely defined by W. B. Cheadle in 1903. Although it has been "rediscovered" and often renamed in other countries, the work done on the disease here has earned the compliment recently paid by Continental and American authors of adopting the title originally proposed by Gee. For these reasons we cordially welcome an important article dealing with the causation of coeliac disease by Drs. Olive MacRae and Noah Morris, which appears in the current issue of the *Archives of Disease in Childhood*,[1] and is entitled "Metabolism studies in coeliac disease."

The problem of the causation of coeliac disease is easily stated. It is known that the disorder arises only in young children, and has never been observed to start in adult life; and that it persists for a varying number of years and then gradually peters out, leaving the patient free from digestive symptoms and presumably able to deal normally with the dietetic fat. It is also nearly certain that coeliac disease does not depend upon organic disease, but is a digestive fault or disorder. It is generally agreed that the essence of the disorder is a failure to absorb properly the fat of the food, and that although carbohydrate and even protein absorption may be interfered with, and vitamin deficiency may develop, these are secondary faults. It is, then, the cause of the mal-absorption of fat which is the problem, and here certain possibilities can be excluded. We know that the pancreas is not at fault, for the failure lies not in the splitting but in the absorption of the fat of the food. It is also certain that the failure in fat absorption is not due to gross disease of the wall of the intestine, as is probably the case in sprue. Another alternative is that of lacteal obstruction, and, although it would perhaps be premature to dismiss this possibility altogether, it is clear that at least there is no gross obstruction to the lacteals, as by enlarged abdominal glands, in this disorder. It has also been suggested that in coeliac disease the fat is really absorbed, and that the fault lies in its re-excretion into the intestine; but this hypothesis, never very attractive, seems to have been disproved.

If we can set aside these various alternatives we are practically forced to conceive that coeliac disease is due to some derangement of hepatic function particularly affecting the action of the salts of the bile. It is known that Cheadle took somewhat this view, for he invented the term "acholia" for the condition, and evidently visualized a suppression of liver function. Since his day it has become obvious that this explanation cannot be altogether correct, for it is known that the pallor of the typical fatty coeliac stool is not due to absence of bile pigment, but to masking of the bile pigment by the excess of fatty acids in the faeces. Actually the point of importance is not a matter of the flow of bile, still less the normality of the bile pigments: what we are concerned with is the activity of its constituent salts. Were we able to prove a deficiency in these, the mal-absorption of fat in coeliac disease would be explained; but it is difficult to imagine that any such deficiency would persist for years, as we should have to postulate; and it is known that the administration of bile salts, though it may improve fat absorption in coeliac disease, does not correct it entirely. O. MacRae and N. Morris, in the paper mentioned above, put forward a novel suggestion—namely, that the reaction of the medium in which the bile salts work is at fault, and that this leads to loss of activity on their part. Such an explanation might well be sufficient to account for the daily variations in fat absorption which can be shown to occur in coeliac disease, but again it is difficult to suppose that this is enough to account for the persistence of the mal-absorption over a period of years. The authors presumably feel this difficulty, for they also postulate a deficiency in bile salts. The results of their metabolic investigations are, they think, best explained by regarding the defect in absorption as due to change or changes in the physico-chemical constitution of the intestinal contents, which changes probably include a shift of reaction to the alkaline side and a deficiency in bile salts.

THE BUDGET

In times of normal national finance the introduction of a Budget is always one of the major political events of the year, and in these days, when the taxpayer is staggering under his burden, hoping for relief, but apprehensive—and often with very good reason—of yet further additions to the load, the unfolding of the Chancellor's fiscal scheme for the coming year is a matter not merely of great political interest, but also one of real anxiety to taxpayers. Particularly is this the case with the upper and upper middle classes, by

whom, in these days of steeply graduated rates of tax, the burden is keenly felt. The lower middle class, as typified by the family with an income of £400 to £600 per annum, is in the main freed from substantial income tax liability by a generous scale of allowances for children, dependent relatives, etc. ; the extremely wealthy will always have a fairly adequate margin of income left after payment of the heavy taxes now in force ; but the intermediate class—of which the medical profession is well representative—probably feels the pinch of high direct taxation as much as any. It is felt by them not merely through the indirect effect on the ability of their clients to make reasonable payment for professional services, but also on account of the real difficulty of finding the cash required for payment without trenching on savings or making uneconomic sacrifices in personal consumption or in the education of their families.

During the past few years the general attitude towards Budget after Budget has been to regard it as " critical," as " dealing with abnormal circumstances," and generally as calling for, or justifying, special treatment. Few have deserved such descriptions so completely as the Budget of 1931. That the financial position is unhealthy and may become dangerous is obvious enough to all thinking persons. The long period of depression in industry is world-wide, and has an increasing effect on Government finances ; on the one hand, it has led to enormously increased expenditure—last year's supplementary estimates for " benefits arising from exceptional unemployment " amounted to £10,000,000—and on the other hand, it is drying up gradually but unmistakably the sources from which such expenditure can be met. It is perhaps unfortunate that, whereas the taxation proposals of a Government are brought to a focus on a single day and thus attract national attention, consideration of the expenditure which determines the extent though not the precise nature of the taxation is diffused throughout the parliamentary year, and the impact of public feeling and criticism on such proposals is thereby rendered of little effect. The device of appointing a Government Economy Committee to take a comprehensive view of them and apply an intensive criticism has been tried more than once, and is being tried again ; but it may be doubted whether the House of Commons can deal effectively with political or semi-political questions by such means. However that may be, the fact is that the Chancellor of the Exchequer on Budget Day, acting in his capacity of financial provider, has the national bill presented to him, and it is his business to devise ways and means of meeting it. This year he is faced by the initial difficulty that there is £23,000,000 still unpaid on last year's account. It is, however, some consolation to remember that that sum is not owing on account of current expenditure, but is the amount by which the nation has failed to pay off as much debt as was intended. Mr. Snowden rightly emphasized the fact that, after allowing for that failure to carry out our good intentions, we had nevertheless applied a sum of £52,500,000 to debt reduction in the past twelve months. In the circumstances that result can be regarded with some degree of complacency, especially in comparison with the corresponding position in some other countries. Mr. Snowden has in the past taken the strong line that any failure to fulfil a debt redemption programme should be made good in the following year, but in the exceptional conditions of to-day he proposes to depart from his own principle, and in that departure, at least, he will not lack for willing followers.

Turning to the coming year, the gap between prospective expenditure and the income which would be received if the present taxes were unaltered is the somewhat alarming amount of £37,366,000, and the problem of how to find that sum, without recourse to drastic increases in taxation, obviously supplies plenty of scope for ingenuity. Mr. Snowden's reputation is that of a strict and somewhat doctrinaire theorist in fiscal matters, and a good deal of speculation has revolved round the question whether and in what way he would solve his problem. He has on this occasion adopted a frankly opportunistic attitude. Over half the prospective deficiency—£20,000,000—is to be taken from the Dollar Reserve, which has been accumulated in the United States as an insurance against possible exchange difficulties in connexion with Great Britain's payments in respect of war debt. £10,000,000 is to be obtained by expediting payment of income tax during the present financial year, and the balance is to be derived from an increase in the petrol tax. In this way Mr. Snowden claims to solve his problem with a minimum of hardship and inconvenience to the nation. Given the hypothesis that the money must be spent and therefore must be found, he may be right—though there have recently been notable converts to the proposal to obtain revenue by a larger extension of customs duties—but if the hardship is the minimum it is nevertheless very real. We are inclined to think that medical practitioners will find this to be so to a greater extent than almost any other section of the community. In the first place, they will obviously suffer from the additional tax of 2d. per gallon of petrol. It is true that reduction in the price of petrol during the past year may mean that the present increase will merely restore a former price level, but it is a serious matter to have a fall in working costs intercepted and cancelled by taxation, and we are unable to see why a medical practitioner should in that way make a special contribution to taxation from which the members of other professions are exempt, because they do not—at least to a substantial degree—make professional use of the taxed commodity. The additional income tax which will become payable during 1931–32 will in many cases be definitely difficult to meet. When income tax was payable at pre-war rates it was in all cases payable in one sum early in the calendar year. The rise in rates that took place during the war led to the system—first applied to payments falling due in 1916—under which firms and individuals (not limited companies) paid income tax in respect of earned income in two equal instalments, the second of which did not become due until July. In future, three-quarters will be payable

in January and one-quarter in July. For example, a married man with two children having an earned income of £1,000 is liable to pay approximately £80 income tax. Whereas hitherto he has paid £40 in January and £40 in July he will now have to pay £60 and £20, thereby making a special contribution to this year's finances of £20. Undoubtedly it is preferable to pay sooner than to pay more, but neither alternative is free from unpleasantness. It is to be hoped that the Inland Revenue authorities will see to it that instructions are issued to ensure that reasonable latitude for payment is allowed, in spite of the pending legislative change, where special circumstances justify it.

The Chancellor has clearly framed his proposals on the assumption that we are passing through a temporary period of trade depression. The success or failure of his scheme must, to a large extent, turn on the duration of that depression. If in twelve months' time industry is definitely on the up grade and unemployment no longer makes such inroads on the public purse, he must have successfully carried the national finances over one of the most difficult periods in our history. If, on the other hand, conditions remain as adverse as they are to-day, he will have made little or no contribution to a solution of the problem which will face him—or his successor—next year, for the expedients by which he is balancing his 1931 Budget cannot, from their very nature, be repeated. With Mr. Snowden's political merits and career we have no concern, but as representing a body of loyal but suffering taxpayers we hope that his opportunism will not prove to have been mistimed.

PATHOLOGICAL SERVICES

The medical provisions of the National Health Insurance system are avowedly incomplete, and in spite of the evidence given by the British Medical Association to the Royal Commission of 1925, successive Governments have not legislated to give the insured person a complete medical service. At the present juncture the prospects of any such legislation appear to recede, and, not for the first time, initiative in providing for a national want must come from a non-official source. One of the most urgent needs is the provision of facilities for laboratory diagnostic help for insured persons. The British Medical Association has recently organized a scheme to this end, and the attention of our readers is directed to the details given in this week's *Supplement* (p. 183). A large number of laboratories, over one hundred, have consented to work to an agreed schedule of fees, which have been set at the lowest figure consistent with efficiency. The scheme provides a wide choice of laboratories, which will enable practitioners to maintain close personal touch with their laboratory colleagues, an essential feature of this work. However attractive to the administrative mind a centralized laboratory may be, its possible economic advantages are greatly outweighed by the lack of that personal contact assured by a less centralized scheme. "Pathology by post" needs at least to be supplemented by a short-range telephone service if it is to give proper value. The Association's scheme secures a considerable measure of this local contact, and, furthermore, it enlists the help of the laboratories of a large number of general hospitals in which the range of work and experience covers exactly the class of investigation likely to be required for insurance patients. More is needed for this purpose than routine bacteriology; an increasingly important part is played in diagnosis by haematology and biochemistry, and under this scheme all such methods are made available. Until the National Health Insurance system is reformed, any cost incurred for diagnostic service must be borne by the individual patient. This doubtless may militate against any extensive use of the service, but the basis of all good treatment is efficient diagnosis, and often some expense incurred in reaching an accurate diagnosis will, by leading to better treatment and shorter illness, repay the outlay many times. Thus, many thousands of anaemic patients are now being treated at much cost and for many months with liver or its extracts, on the assumption that their anaemia is of the pernicious type. In a not inconsiderable proportion of these, a blood examination would reveal the non-pernicious character of the anaemia, and the cost of treatment could sometimes be reduced. Examples might be multiplied. Few doctors will dispute the advantage of having facilities for laboratory assistance in their work among insured persons and their dependants; and it is the hope of the British Medical Association that these efforts to establish an economical and widespread service will become generally known.

THE MEDICAL EXAMINATION OF DRUNKEN MOTOR DRIVERS

When in 1921 legislation dealing with motor traffic was revised in Denmark, the proposal that drunken motor drivers should be subject to certain penalties raised the question of an expert medical examination. In the following year the Danish Medico-Legal Council laid down certain lines for such an examination, insisting that, with the help of the elaborate scheme proposed, any practitioner should be able to undertake it. In practice, however, this work has devolved on only a few doctors, partly because personal experience and a certain routine were found to be of importance in achieving uniform results, partly because the average practitioner had obviously no taste for this work. Dr. J. Fog, attached to the Medico-Legal Institute in Copenhagen, in an account[1] of 1,000 such medical examinations (spring of 1922 to the middle of 1930), carried out in every case at a police station, shows that the average duration of such an examination, not including the time taken to fill in the report, was about half an hour. A policeman, acting as a witness in the case, was always present. Among the 1,000 persons examined, there were only three women—a ratio much below that of the ratio of all female to all male drivers. The three women were young. Of the persons examined 746 were between the ages of 20 and 40, the extremes being 18 and 60 years. The professional drivers were approximately twice as numerous as the amateurs. There were as many as 685 cases between the hours of 8 p.m. and 8 a.m. Yet there were of course many more cars in use by day than by night. As many as 209 of the 685 night examinees were examined between midnight and 2 a.m. In other

[1] *Ugeskrift for Laeger*, March 12th and 19th, 1931, pp. 284 and 313.

words, about 21 per cent. of all the examinations were carried out in these two early hours of the morning, soon after the closing of restaurants. In 208 cases the person examined was found to be intoxicated. In 591 cases, or 59 per cent., he was found to be more or less under the influence of alcohol, and in 201 cases, or 20 per cent., he was found to be sober or not demonstrably influenced by alcohol. This last group was comparatively large, partly because several drivers themselves asked for a medical examination in order to clear themselves of suspicion, and partly because the police insisted on such an examination in certain serious cases in order to get the matter cleared up as thoroughly as possible, even when the person concerned was obviously sober. Yet another reason for the large size of the last group was the application of the principle of giving an accused person the benefit of the doubt.

JEAN BAPTISTE BOUILLAUD

At the last meeting of the Section of the History of Medicine of the Royal Society of Medicine, Dr. J. D. Rolleston delivered an address, entitled "Jean Baptiste Bouillaud (1796-1881): a pioneer in cardiology and neurology." While modestly disclaiming any proficiency in either of these two specialties, he stated that he had chosen this subject in the capacity of a liaison officer between the Société française d'Histoire de la Médecine, of which he was a member, and the Section of which he had been formerly president. Although Bouillaud's name was familiar to every French medical student owing to its association with acute rheumatism, a knowledge of his work, and even of his name, appeared to be exceptional in this country. At the commencement of his career Bouillaud (like Bretonneau and Velpeau) had a hard fight with poverty, during which he served as the original of Balzac's Horace Bianchon; but later he attained the highest professional honours, being appointed in turn professor of clinical medicine, dean of the Paris Faculty of Medicine, president of the Académie de Médecine, member of the Institut de France, and president of the First International Medical Congress, as well as Commander of the Legion of Honour. Bouillaud's contributions to cardiology were summarized by Dr. Rolleston as follows: (1) the first description of the endocardium and endocarditis, which appeared in his *Traité clinique des Maladies du Cœur*, published in 1835; (2) the establishment of the "law of coincidence," according to which acute endocarditis, pericarditis, or endopericarditis was the rule in acute generalized articular rheumatism; (3) his careful studies of the heart, whereby he created a new department of topographical anatomy; (4) the importance which he attached to auscultation in examination of the heart in contrast with Laennec, who underestimated its value in cardiac, as distinct from pulmonary, disease; (5) his description of new signs, such as "bruit de diable" in chlorosis, "bruit de rappel" in mitral stenosis, and gallop rhythm; and (6) his detailed account of congenital cardiac disease. As a pioneer in neurology Bouillaud identified the anterior lobes of the brain as the seat of speech thirty-six years before Broca, who, though more exact in his localization, acknowledged his indebtedness to Bouillaud. Bouillaud's other chief contributions to medicine consisted in marking out more clearly than any previous observer the domain of acute rheumatism and the importance which he attached to chemistry and physics in medicine, in contrast to Trousseau, who was inclined to depreciate these studies. In conclusion, Dr. Rolleston attributed the oblivion into which Bouillaud had fallen in this country—where, according to contemporary literature his doctrines did not meet with much approval—to his method of repeated and free venesection, with which he persisted throughout his long career. The address was illustrated by portraits of Bouillaud at different stages of his career.

A VISIT TO RHINELAND SPAS

At the invitation of the Rhineland spas (writes a correspondent) a party of medical men, to the number of nineteen, left London on April 1st for Aachen. After a brief stay there they journeyed by car to Neuenahr, Homburg, Nauheim, and Wiesbaden. At each and all of these spas the visitors were received with the greatest enthusiasm. At Aachen an address by Dr. Anton Lieven included some details of the history of the ancient town, as well as a most interesting account of the treatment there. The springs at Aachen are hot, and contain largely sodium bicarbonate, sodium chloride, and various sulphur compounds. They are found to be of great value in the treatment of rheumatic affections in various forms. The waters are used both internally and externally. There is a useful institution at Aachen, where 350 beds are arranged for insured patients, and are paid for at the rate of 7.50 marks daily. This is virtually a research hospital for arthritis, where the work is carried out by a full-time medical staff with all the usual ancillary services; 3,200 patients pass through the institution every year. One method there which invites success is the formation of an association, consisting of the doctors, the hotel directors, and the kurhaus directors, where the system of treatment, housing, and dietetics is co-ordinated. At Neuenahr the visitors were shown a complete unit contained in the hotel—consulting rooms, baths, *x*-ray apparatus, open-air playground, solarium, and swimming baths. The waters are hot and alkaline, and are useful in treating cases of gastric and intestinal dysfunction, as well as rheumatic affections. It is claimed that cases of diabetes mellitus are benefited by these waters. From Neuenahr the ancient university town of Bonn was visited, and Professor Jansen showed the Hospital St. Marie, where both free and paying wards are to be found. The party next were taken to Homburg, a town which has many English attributes, and is closely linked with the memory of King Edward when he was Prince of Wales. Here the dietetic treatment of disease is stressed in addition to the waters, and at one private sanatorium the visitors were invited to sample an elaborate display of uncooked dishes. They next visited the delightful town of Nauheim, celebrated for its carbon dioxide baths for the treatment of cardiac disease. There is here a cardiac research institute, under the direction of Professor Weber, which is fully equipped with modern apparatus, one of the many interesting features being a loud-speaking phonendoscope from which the heart sounds are broadcast. A second institute is about to be opened for cardiological research, which has been amply endowed by private enterprise. It struck most of those who

visited these two institutions that they afforded an unrivalled opportunity for cardiological study, and that Nauheim ought to become in the future even more widely known as a centre for investigation and treatment of heart disease. Lastly, they came to Wiesbaden, a large, agreeable, clean town, noted for its many warm alkaline springs, which are used chiefly in the treatment of rheumatic affections. A motor run to Mainz was followed by a whole day's journey by steamer to Cologne, and so home. It must be understood that after reaching the German frontier the party were the guests of the Rhineland spas above mentioned, whose lavish hospitality they enjoyed. The success of the trip was largely due to the efforts of the organizing secretary, Mr. R. O. Rohne.

THE "VETERINARY BULLETIN"

Students of comparative medicine will be interested to hear of the appearance of the first issue of the *Veterinary Bulletin*, a quarterly publication issued under the auspices of the Imperial Agricultural Bureaux. This bulletin replaces the *Tropical Veterinary Bulletin*, but its scope is extended to include abstracts of current papers on diseases of animals in all parts of the world. It will not review clinical papers from the point of view of the practitioner; otherwise it deals with all aspects of animal health in so far as they relate to original research and to administrative control. Some of the abstracts in the first issue scarcely seem to come within the purview of the *Bulletin*, but on the whole the papers are well chosen and of general interest. The *Bulletin* should fulfil a very useful function, and be of value alike to veterinarians and medical men. It is published at an annual subscription of £1, and is obtainable from the Imperial Bureau of Animal Health, Veterinary Laboratory, Weybridge, Surrey.

SOCIETY OF APOTHECARIES

The Society of Apothecaries of London entertained in its Hall at Blackfriars a large and distinguished company at a Livery Dinner on April 28th. The guests were received by the Master, Lieut.-Colonel C. T. Samman, and the senior and junior wardens, Colonel E. C. Freeman and Dr. Cecil Wall. After the loyal toasts had been honoured, Sir Stanley Hewett, K.C.B., K.C.V.O., K.B.E., Surgeon Apothecary to the King, was presented to the Master by Sir William Willcox to receive the diploma of the Society *honoris causa*. This honour, Sir William Willcox said, had only twice before been conferred: on H.R.H. the Prince of Wales, and on Sir John Lynn-Thomas as representing surgery. It gave him great pleasure to present Sir Stanley Hewett, whose devotion and skill during His Majesty's long illness two years ago had won the gratitude of the whole British Empire. The toast of "The Civil Service" was proposed by Mr. Arthur Greenwood, Minister of Health, who took this opportunity of paying a warm tribute to those who were so often and so unfairly attacked in public under such epithets as "a bloated bureaucracy." Nowhere in the world, he said, could there be found public servants more trustworthy, honourable, and devoted to the common good than those who made up the British Civil Service. It was manned by a body of English gentleman, whose one aim was to serve the State and be loyal to ever-changing political chiefs. Mr. Greenwood expressed, in conclusion, his personal debt to Sir Arthur Robinson, Secretary to the Ministry of Health, who responded to the toast in historical vein. In proposing the health of "The Guests" Sir George Makins welcomed by name many of those whom the Society delighted to honour that evening, and coupled with this toast the names of Lord Ebbisham, a former Lord Mayor of London, Sir John Bland-Sutton, Bt., and Mr. Cecil Whiteley, K.C., who each briefly made their acknowledgements.

JOURNÉES MÉDICALES DE BRUXELLES

Special interest attaches this year to the congress known as the Journées Médicales de Bruxelles, which will be held from June 20th to 24th, in that it will commemorate the work of Fernand Widal. As in previous years there will be an impressive programme of practical and theoretical lectures and demonstrations on various medical and surgical topics, and the late Professor Widal's colleagues and scientific friends will take a prominent part in these. At the opening meeting on June 20th Professor Vaquez will deliver an address. On the last day of the congress a visit will be paid to Spa, where the baths will be inspected, and the formal opening of Professor Henrijean's laboratory will be attended. The congress will include the usual social functions, and its success is already assured by the number of distinguished men of science who have promised to take part in the proceedings, and so to honour the name of Professor Widal. The fee for membership is 75 francs; it is payable to the general secretary of the congress, Dr. Beckers, 145, rue Belliard, Brussels, from whom further information may be obtained.

We much regret to announce the death, on April 27th, in his eighty-fourth year, of Sir Byrom Bramwell, M.D., consulting physician to the Edinburgh Royal Infirmary, and a corresponding member of many foreign neurological societies. We hope to publish a memoir in our next issue.

Professor Samson Wright will deliver the Oliver-Sharpey lectures before the Royal College of Physicians of London on May 5th and 7th at 5 p.m. His subject is "Certain aspects of the reflex control of the nervous system."

As already announced in these columns, a series of five lectures on "The rise of preventive medicine," under the terms of the Heath Clark Bequest to the University of London, will be given in the London School of Hygiene and Tropical Medicine, Gower Street, by Sir George Newman, K.C.B., M.D., Chief Medical Officer of the Ministry of Health and the Board of Education. The dates and subjects of the lectures are as follows: May 4th, Folk-lore, magic, and custom; May 5th, Egyptian medicine and the Mosaic Law; May 6th, The Greek science and the Greek spirit; May 7th, Their transmission and transmutation; May 8th, Famine pestilences, leprosy, and the Black Death as early practical problems. The chair at the first lecture, on May 4th, will be taken by the Minister of Health. All the lectures commence at 5 o'clock, and are open to the public without ticket.

Nova et Vetera

A LINK WITH PASTEUR

When Professor Jules Bordet was in London in December, 1930, giving his Croonian Lecture, he discovered that the Royal Society did not possess an autograph of Louis Pasteur. Accordingly he communicated with Dr. Roux, director of the Pasteur Institute, suggesting that he might be able to send a suitable document for presentation.

In due course the Royal Society received from Dr. Roux a letter which was addressed to him by Pasteur in 1886. A copy is reproduced below, through the courtesy of Dr. H. H. Dale, secretary of the Society. It is interesting to note the appropriateness of this autograph, because it is probable that the letter refers to the first English patients who received the Pasteur prophylactic treatment for hydrophobia—" la petite Tattersaal " and " le petit Walter Sykes."

This gift from two distinguished Foreign Members of the Royal Society will appeal to all in the medical profession, and their generosity and kindness will be fully appreciated.

Letter from Pasteur to Roux

Arbois, le 1er Sept. 1886.

Mon cher Roux,

N'abandonnez la petite Tattersaal que cinq semaines après sa morsure. C'est vous dire que vous demanderez à sa mère, de ma part, qu'elle veuille bien après le traitement actuel rester encore à Paris pendant quelques jours et terminer par un dernier traitement de trois à quatre jours. (Sa blessure est-elle guérie?) J'ai promis à sa mère de l'aider si elle n'a pas assez d'argent. Demandez-lui ce dont elle a besoin. Notez vos avances avec soin.

Je vous ai donné des instructions pour le petit mordu par le chat, dans ma lettre d'hier.

Traitez le petit anglais Walter Sykes à la manière de Tattersaal et de l'enfant mordu par le chat.

On me demande instamment des nouvelles de la santé des mordus suivants (tous du Pas de Calais) par le même chien enragé, le 16 Août:

1. Nathalie Courcelles, 51 ans.
2. Edouard Courcelles, 11 ans.
3. Virginie Courcelles, 9 ans.
4. Théophile Courcelles, 7 ans.
5. Jean-Baptiste Capron; mordu le 14 Août.
6. Siméon Capron, mordue le 11 id.
7. Maria Conte, 17 ans; mordué le 16 id.
8. Leon Dumont, 3 ans; mordu le 16 id.

N'hésitez pas à retenir ces personnes pour un second et un troisième traitement, si vous avez des blessures sérieuses.—Elles ont beaucoup tardé à venir, parait-il.

J'ai repondu à l'Ambassade Anglaise que le labre est fermé—vacances—Reprise du travail fin Oct.—Alors, à la disposition de l'officier vétérinaire—qu'en ce moment service seul de la rage en activité.

Mille bonnes amitiés

L. PASTEUR.

ROYAL MEDICAL BENEVOLENT FUND

During the first quarter of this year the sum of £3,650 has been voted in grants to applicants, as against £2,562 during the corresponding period of last year. Subscriptions received during the same period amounted in 1931 to £2,499, but in 1930 to £2,628. New subscriptions and donations are therefore very urgently needed, and should be addressed to the Honorary Treasurer, Royal Medical Benevolent Fund, 11, Chandos Street, Cavendish Square, W 1.

At the April meeting the committee voted £795 to forty-five applicants.

One recipient was a widow, aged 43, with a daughter, aged 9, who called at the office of the Fund. Her story (which has since been verified in every detail) was as follows. Her husband qualified in 1914, and served throughout the war in the R.A.M.C. He was wounded in 1915, and was four times mentioned in dispatches. The latter part of his service was with the British Military Mission in Siberia; while there he married a Russian lady who was engaged in Red Cross work in Siberian hospitals. After demobilization he practised in the Far East from 1919 to 1930. He went into his little daughter's room to open a window, and stood on a child's chair. The shutter was stuck, but suddenly opened, the child's chair broke, and the father fell out of the window on to a roof two floors below. He died within twenty-four hours, at the age of 42. After the practice was sold, and by the time his widow and child had returned to England, it is expected that the estate will yield an income of £70 a year. The first dividend not being payable till June, the Fund immediately gave a grant of £26 to the widow, and arranged with another charity to give a similar sum to tide her over the present difficulty. The Royal Masonic Institution has undertaken the education of the child. Employment is very urgently needed for the widow; beyond the experience gained by Red Cross work in hospitals, she speaks English and French fluently as well as Russian. She is willing to take up any work, being practical and of gentle birth.

The Royal Medical Benevolent Fund Guild still receives many applications for clothing, especially for coats and skirts for ladies and girls holding secretarial posts, and suits for working boys. The Guild also appeals for second-hand clothes and household articles. The gifts should be sent to the Secretary of the Guild, Tavistock House (North), Tavistock Square, W.C.1.

Ireland

Annual Meeting of the British Medical Association, Dublin, 1933

A very successful meeting of representatives of the medical profession and of scientific and municipal bodies was held recently in the Board Room of the Royal College of Surgeons, Dublin, for the purpose of making preliminary arrangements in connexion with the Annual Meeting of the British Medical Association in 1933, which it is proposed to hold in Dublin. Dr. T. Gillman Moorhead, President of the Royal College of Physicians of Ireland, and of the Leinster Branch of the British Medical Association, occupied the chair, and explained that the reason for calling the meeting at that date was that the necessary organization would demand hard work during the intervening period. In addition to a general committee, with officers, about nine or ten other committees would have to be appointed. At present the membership of the British Medical Association was just short of 36,000; by 1933 he expected it would have increased to 40,000. He could safely say that the British Medical Association was the most important medical association in the world. In Ireland there were 1,000 members, but that did not exhaust the number of Irish members, because throughout the world, wherever there were Branches of the Association, they found Irishmen taking a very active part in the business of those Branches. Apart from their professional interest, these Annual Meetings of the Association had also a civic and national importance. In Winnipeg last year the visit of the Association was regarded as the culmination of three years' effort, and those who attended that meeting had been given what amounted to civic receptions in every town. They did not expect to do things on such a gigantic scale in Dublin, but they had to realize the necessity for making adequate preparation for a meeting which would be attended by about three thousand medical men with their families, and by many distinguished men of science from other countries. All these visitors must be given a favourable impression of Ireland. Their visit

would act not only as a stimulus to the medical profession and to their medical schools but to their trade generally, and he believed that great benefits would accrue to the tourist traffic in future years. They had had five visits from the Association since its foundation a hundred years ago. The last Annual Meeting held in Dublin took place in 1887, so that another Annual Meeting in that city was long overdue. That fact would encourage everyone to make the coming visit one of the greatest in the history of the Association.

The Lord Mayor of Dublin proposed that those present should be formed into a general committee, and said that they had not started one moment too soon in organizing a meeting of such magnitude. The medical profession, he was sure, would have the support of all sections of the community. He promised to give all his personal assistance, and placed at their disposal whatever accommodation the Mansion House afforded for meetings or other work. In seconding the resolution, Sir William Taylor said that they could look forward to the visit of about six thousand people, and he was certain that many of these, after the meeting had concluded, would spend some time in Ireland visiting the holiday resorts. Next to the Eucharistic Congress, he regarded the visit of the British Medical Association as the greatest asset to the Free State. In proposing that Dr. J. P. Shanley and Professor J. W. Bigger should be appointed joint honorary secretaries, Dr. D. J. Coffey, president of University College, said that they were bound to ensure the success of this visit of the British Medical Association. They were too much bound up with the medical profession in England and Scotland to afford to miss any opportunity of strengthening these ties. Dr. R. J. Rowlette, who seconded the resolution, said that this visit of the British Medical Association was a matter of even greater importance to the community in general than to the medical profession. It was not merely as a favour, but as a duty, that they asked the non-medical public to throw itself into the work of organization ; if they were to succeed as they hoped, it was necessary that there should be the heartiest co-operation. The resolution was passed unanimously. On the proposal of Mr. R. A. Stoney, President of the Royal College of Surgeons in Ireland, Dr. W. D. O'Kelly and Alderman Hubbard Clark were appointed honorary treasurers, and, on the motion of Professor Henry Moore of University College, seconded by Dr. Kathleen Lynn, the following were appointed the executive committee, with power to co-opt : Dr. T. G. Moorhead, Dr. J. P. Shanley, Dr. J. W. Bigger, Mr. Doolin, Sir William I. de Courcy Wheeler, Mr. H. F. MacAuley, Mr. C. J. MacAuley, Dr. R. J. Rowlette, Dr. R. C. Peacocke, Sir William Taylor, Dr. D. A. MacErlean, Dr. Bethel Solomons, Sir James Craig, Dr. M. J. Cuffe, Dr. P. MacCarvill, Dr. T. Hennessy, Dr. M. J. Russell, Dr. Lombard Murphy, Professor A. F. Dixon, Alderman Hubbard Clark, Dr. Kathleen Lynn, Mr. J. M. Devitt, and Mr. Denis Barrett.

Dr. R. C. Peacocke proposed a vote of thanks to those bodies which had sent delegates to the meeting. He pointed out that it was not a meeting of specialists, but of general practitioners as well. He had been assured by Dr. Cox, the Medical Secretary of the British Medical Association, that the members generally were looking forward to their visit to Dublin, and it was up to the people in Ireland to make that visit as pleasant and memorable as possible. A letter was received from General R. Mulcahy, Minister for Local Government and Public Health, expressing regret at his inability to be present, but he assured the meeting that the British Medical Association would receive a cordial welcome from the Executive Council of the Irish Free State Government.

Gift from Northern Ireland Medical Practitioners to the Royal Medical Benevolent Fund in Ireland

At a meeting of the managing committee of the Royal Medical Benevolent Fund Society of Ireland, held recently in the Royal College of Surgeons, Dublin, the secretary was directed to express the committee's grateful appreciation of the generous action of the practitioners of Northern Ireland in handing over the sum of £100 8s. 6d. as a contribution to the society, this sum representing the assessed proportion of the funds of the Irish Medical Committee due to Northern Ireland, with accrued interest. The committee also expressed thanks to Mr. R. J. Johnstone, F.R.C.S., for his letter of March 30th, enclosing a cheque for the above amount, and asked him to convey to those concerned its gratitude for the gift and its appreciation of the gracious sentiments which inspired it.

Medical Appointment in County Roscommon

The medical officers of the County Roscommon Board of Health have issued an appeal to medical candidates for the Rooskey Dispensary district to withdraw their applications in the interest of Dr. Annie B. Mullen, wife of Dr. John Mullen, who resigned lately from Rooskey district as the result of a serious illness. The appeal states that Dr. Annie B. Mullen before her marriage was medical officer of the Baltinglass district in County Wicklow, and that she discharged her duties to the entire satisfaction of the Department of Local Government and Public Health and the County Wicklow Board of Health. The appeal also states that she is responsible for the maintenance of her invalided husband, who has been in a medical institution since the commencement of his incurable illness.

Scotland

University of Glasgow

The report of the General Council of Glasgow University states that the total revenue of the University for 1930 amounted to £256,475, with an ordinary expenditure of £256,879. The total number of students in the year 1929-30 was 5,526 (thirty more than in the previous year), while the number of degrees granted was 1,191 (an increase of 210). Comment is made upon a draft ordinance containing regulations for a science degree in pharmacy. With some minor changes the report recommends that this proposal should be approved by the University Court. It also suggests the establishment of a Glasgow University Club to enable persons interested in the University to maintain closer contact. At least 500 members, it is estimated, must be enrolled in order to make the institution of such a club feasible.

Opening of Dunfermline Hospital

The opening of the new extension to the Dunfermline and West Fife Hospital was performed on April 22nd by Sir Ralph Anstruther, Bt., Lord-Lieutenant of the County of Fife. Mr. Brownlie, chairman of the Board of Management, who presided, said that Dunfermline now possessed an institution which for its size and class was second to none in the country. The design and execution of the buildings reflected great credit on Colonel D. J. Mackintosh, superintendent of Glasgow Western Infirmary, who had acted as consultant architect and consultant medical adviser. An appeal for £50,000 had been issued, and an equipment fund amounted to £20,000. Not only would the hospital be opened free of debt, but the greater

part of the latter sum would be available for endowment. The number of beds would be one hundred, and he was confident that the increased contributions required for their maintenance would be forthcoming. In declaring the extension open Sir Ralph Anstruther remarked that the appeal for the extension fund had met with an extraordinarily fine response. This fact seemed to indicate that the proposal to put hospitals on the rates would be a retrograde step. The voluntary system had not only provided the necessary hospital accommodation, but it had a fine effect upon all who took a share in carrying out the work. In urging the hospital authorities to consider the admission of paying patients, he said there were a great many people who would be glad to take advantage of the hospital services if they were allowed to defray some of the expenses. The main part of the extension consists of a new administrative block and two new wards, which were completed a year ago at a cost of £50,000. Since then the old part of the hospital has been completely reconditioned and equipped, and an extensive out-patient department has been added at a cost of about £10,000. One of the features of the new hospital is the operating theatre, which contains the latest surgical equipment. The *x*-ray apparatus cost £1,500, and the *x*-ray rooms are so arranged that plates are ready to view seven and a half minutes from the time the photograph is taken. A new nurses' home has also been provided by the extension and renovation of the neighbouring Priory House, a private residence which was presented as a gift to the hospital.

Nursing Conference

In connexion with the Scottish nursing, hospital, and health week, from May 24th to 30th, a comprehensive refresher course of lectures for nurses has been arranged. These will include lectures on the future training and organization of nurses, by Dr. J. Parlane Kinloch, chief medical officer of the Department of Health for Scotland; on the public health services, by Dr. John Guy, medical officer of health for Edinburgh; and on the maternity service, by Dr. A. S. M. Macgregor, medical officer of health for Glasgow. Lord Provost Whitson will open the conference in the Music Hall, Edinburgh, on the first day, and among the subjects to be discussed are: treatment of mental disease, orthopaedics, tuberculosis, surgical conditions in childhood, remedial exercises, and the legal position of nurses. The programme includes visits to the special departments of the Royal Infirmary, Edinburgh, and to other hospitals and institutions.

England and Wales

Cancer Research in Manchester

The annual report for 1930 of the Manchester Committee on Cancer includes a brief summary of the work done by the scientific staff and at the Christie Cancer Hospital and Home, the only hospital in England outside London which is entirely devoted to the investigation and treatment of cancer. Research work during 1930 was mainly devoted to the further study of mule-spinners' cancer and to the cancer-producing properties of mineral oils, to remove the harmful products of which, economically and without diminishing their lubricating qualities, special efforts have been made. The Anglo-Persian, Anglo-American, and Shell-Mex Oil Companies, in making a joint contribution of £1,000 for two years to the Research Committee, have recognized the commercial significance of the work being done at Manchester. These companies have also provided the laboratory with crude oils from all over the world, and are, in their own research laboratories, purifying samples of oils according to the suggestions of the scientific staff of the Manchester Committee. It has been found that the cancer-producing action of mineral and lubricating oils can be greatly increased by only relatively slight heating, and that the addition of oleic acid to a synthetic tar possessing high carcinogenic powers has a similar effect. It is thought that oleic acid itself may have carcinogenic properties, though it enters into the composition of the majority of non-carcinogenic animal and vegetable fats. Methods of detoxicating lubricating oils include treatment by sulphuric acid and by clay, the addition of animal to mineral oils, and exposure to ultra-violet light and radon. It has been found that a very large quantity of acid is required to detoxicate carcinogenic mineral oils, whereas only 5 to 10 per cent. by volume of sulphuric acid is necessary to lessen the potency of lubricating oils by as much as 75 per cent. Mineral oils obtained from petroleum wells show considerable variation in activity. The important factor is thought to be the chemical composition of the oil, and an attempt is being made to estimate the carcinogenic activity of oils by combined physical and chemical methods. In the opinion of the Manchester Research Committee there is definite evidence of the curative value of radium in the treatment of cancer, even in cases which have been beyond the sphere of purely surgical treatment. The report states that there is every prospect of cure in the earlier stages of the disease by the use of radium and of surgery, and more especially by a combination of the two. In response to an appeal made in Lancashire, Cheshire, and North Wales, £24,700 has been subscribed for cancer research in Manchester, £2,000 of which has been set aside for the investigation of the uses of radium.

Functions Transferred to the Welsh Board of Health

A matter of interest to Wales and Monmouthshire appears in a circular issued from the Ministry of Health under the date of April 20th, 1931, wherein it is stated that the Minister has arranged to transfer to the Welsh Board of Health his functions in relation to: (1) surveys of public health services in Wales for the purpose of Section 104 of the Local Government Act, 1929; (2) all proposals relating to Poor Law medical work and the provision of new hospital accommodation under the Public Health Acts, with the exception of those proposals relating to the superannuation and compensation of officers, and questions affecting the status, tenure of office, powers of the council in regard to remuneration or dismissal, and conditions of service generally, which may arise under Section 121 of the Local Government Act, 1929, in regard to the position of officers transferred to the service of councils under Section 119 of that Act. The transferred Poor Law medical work covers:

1. Administration of outdoor medical relief.

2. Appointment, dismissal, tenure of office, conduct and conditions of service (with the exceptions indicated above) of (*a*) medical officers, (*b*) nurses, (*c*) dispensers, (*d*) all other officers of institutions for the sick (excluding persons of unsound mind and mental defectives), and sick wards of other institutions.

3. Approval of Poor Law institutions for teaching probationer nurses.

4. Infectious diseases in Poor Law institutions.

5. Provision, extension, or alteration of all accommodation for the sick (excluding persons of unsound mind and mental defectives).

Correspondence

CHOLECYST-GASTROSTOMY

SIR,—The article headed "Four biliary anomalies: a plea for cholecyst-gastrostomy," appearing in the *Journal* of April 18th, gives an account of four very interesting cases, and finishes with a commentary wherein the authors stress the value of cholecyst-gastrostomy in certain circumstances.

Having been for about seventeen years a very confirmed advocate of the operation, I would like to say, first of all, that it is to America we owe its initiation and its chief practice as a method of biliary tract drainage (in the absence of jaundice) due to pancreatic obstruction of the common bile duct. In my view, the operation should be performed in all cases where the gall-bladder is in good condition, and when well-marked pancreatitis is present (*Journal*, 1930, i, 1009). After a large experience of cholecyst-gastrostomy performed for gastric and duodenal ulcer, I am in a position to say a word about its difficulty and its risk. In my hands Smith's clamps, with the small half-circle curve, have proved the best, though there are many cases where it is not easy to apply a gastric clamp at all. When the gall-bladder has no complete peritoneal covering towards the fundus it is easy and helpful to mobilize the organ by lifting it from the liver bed and hinging it on the cystic duct. The operation mortality in the hundred cases done for gastric and duodenal ulcer has been only 2 per cent.

I think it not quite right to infer that the physiologists as a whole (as judged by their textbooks) have the honour of being the first to show the normal regurgitation of bile which takes place in all of us between two and three hours after food. I suggest that the physicians and surgeons, chiefly by the Reyfus tube, have the prior claim.

In 1914 my colleague Mr. Collinson and I reported three cases in which the duodeno-jejunal junction had been divided, both ends closed, and a gastro-jejunostomy performed (*British Journal of Surgery*, vol. i, No. 1, p. 665). In none of these cases was there any vomiting, despite the fact that the *whole* of the bile and pancreatic juice passed through the stomach. The real difficulty, so long as there is no obstruction in the common duct, is to keep the anastomosis open. As the authors of the paper say, the anastomosis can easily be detached. In my experience the mucous tract separates itself in about eighteen months, and to this difficulty (in dealing with gastric and duodenal ulcer) I have been applying myself the last few years. It has been said—in experiments in dogs it has been proved—that there is a danger of liver infection via the gall-bladder. *X* rays have shown that permeation may occur, but I have never had a case, or read of one, where this has happened and given rise to symptoms.—I am, etc.,

Leeds, April 21st. L. R. BRAITHWAITE.

BLOOD PRESSURE AND LIFE ASSURANCE

SIR,—The life assurance company of which I am chief medical officer sends out instructions for the taking of blood pressures identical with those mentioned by Major G. R. McRobert in his letter published in the *Journal* of April 25th. May I therefore briefly explain why the medical examiners are asked to record the diastolic pressure at the point "at which all sounds disappear"?

The company in question is Canadian, and follows the practice universally adopted in America. When the American companies first asked their examiners to take blood pressures they found that the figures recorded, especially those of the diastolic pressures, were so inaccurate as to be of little use for statistical, or, indeed, for any other purposes. It was therefore decided to ask all examiners to record the diastolic pressure at the point of disappearance of all sound. The medical advisers of the companies were perfectly well aware that this point did not represent the true diastolic pressure, but they felt that it was a point that could be accurately recorded by even the most inexperienced examiner. The resulting records are probably about 10 mm. below the true diastolic pressure in the majority of cases; but, if an unduly high figure is returned, it is certain that a raised diastolic pressure is present. The statistics referred to in the memorandum quoted by Major McRobert are intended for the use of life assurance companies, and for their purpose accurate and consistent records are essential.

My experience in reviewing medical reports on applicants for life assurance convinces me that there is still a large number of medical men who do not understand the correct method of estimating the diastolic pressure. It is far more useful to know that all sound disappears at, say, 85 mm., than to receive a highly inaccurate estimate of the true diastolic by an examiner who has had little experience with the sphygmomanometer. I have quite frequently seen diastolic pressures of 120 mm. recorded in cases which are recommended by the examiner as "first class," and on several occasions I have been asked to believe that the diastolic is higher than the systolic.

No doubt the time will soon arrive when true diastolic readings of the blood pressure can be accepted with as much confidence as readings of the pulse rate. In the meantime many companies prefer to make use of an arbitrary point which is easy to record and which does, at any rate, give some indication of the true diastolic pressure. I hope that what I have said may be useful to others who, like Major McRobert, have been surprised to find an apparently elementary "error in a memorandum issued by an insurance company."—I am, etc.,

London, W.1, April 27th. MAURICE E. SHAW.

MULTIPLE EXOSTOSES OBSTRUCTING PARTURITION

SIR,—In his interesting account of a case of multiple osteochondromata with obstructed labour (*Journal*, April 25th, p. 704) treated by Caesarean section in Cyprus, Dr. Blackaby comments on the rarity of multiple bony tumours of the pelvis causing obstruction to parturition. A few years ago an exhaustive analysis of the medical literature dealing with osteochondromata, multiple and single, was made,[1] and it may be of interest to Dr. Blackaby and others of your readers to cite some of the results of this search in so far as they concern the pelvis.

Some 431 cases of multiple exostoses were reported up to 1924, and the pelvis was the site of one or more of the growths in 79 of these. The ilium was affected in 79 per cent. of cases, the pubis in 14 per cent., and ischium in 7 per cent. The pelvis was involved in males in 47 out of 274 cases, and in females in 29 out of 129 cases. In 26 of the cases having a pelvic growth, where there was a complete record of the location of the other exostoses, the mean number of other bones with exostoses was 7; these included the tibia in 25, femur in 23, fibula in 19, humerus in 19, small bones of the hand in 18, radius in 17, ulna in 16, scapula in 16, clavicle in 13, ribs in 11, small bones of the foot in 8, sternum in 4, vertebrae in 4, and cranial bones in 3. In 506 cases having an isolated osteochondroma on some bone other than the cranium, the pelvis was the site in 45. In 94 cases of multiple enchondromata the pelvis was the site of one or more growths in 6.

[1] Stocks, P., and Barrington, A.: Hereditary Disorders of Bone Development. *Treasury of Human Inheritance*, vol. iii, Part I. Cambridge University Press. 1925.

An examination of the detailed records of 100 pairs consisting of parent and child exhibiting multiple exostoses showed that the parent had an exostosis on the pelvis in 14 and the child in 14, and in 4 of these instances the pelvis was affected in both members of the pair,. the expected number of coincidences on the basis of a random distribution being 2. The records of some 300 cases of multiple exostoses with hereditary history show that a single exostosis was found on the pelvis in 29, and more than one exostosis on the pelvic bones in 25. Of the latter, 14 were males and 11 females. In most of the male cases the growths were noticed only on the ilia, usually on the crests or near the anterior superior iliac spines, but in 3 cases they were found in other parts of the pelvis also.

Besides the 11 female cases with multiple pelvic exostoses mentioned above, at least 3 more female cases have been described, not having any clear history of heredity. These 14 cases were recorded by Vix, 1856 (Giessen); Kormann, 1874 (Berlin); Heymann, 1886 (Berlin); Drescher, 1889 (Zur Casuistik der hereditären multiplen Exostosen, Inaugural Dissertation, Giessen); Barthélemy, 1890 (Paris); Hirst, 1894 (U.S.A.); Stérin, 1902 (Lille); Lippert, 1903 (Leipzig); Porak and Daniel, 1903 (*Comptes-rendus de la Soc. d'Obstétrique, de Gynécologie et de Pédiatrie de Paris*, v, 52); Gossage and Carling, 1910 (London); Delfino, 1913 (Hamburg); Marshall, 1916 (U.S.A.); Ehrenfried, 1917 (U.S.A.); Buchanan, reported by Ehrenfried, 1917 (U.S.A.).

Interference with normal parturition was occasioned by these exostoses in the case described by Porak and Daniel, a woman, aged 21, requiring symphysiotomy, and in Drescher's case, a woman, aged 30, who died after childbirth, and was found at necropsy to have several exostoses on the inner surfaces of the symphysis pubis and right iliac fossa, together with numerous exostoses and a few enchondromata on other bones. The references to these two cases are given above.

I know of no other case recorded prior to 1924 in which multiple bony growths on the pelvic bones were associated with obstruction to parturition, and Dr. Blackaby's case therefore presents a combination of circumstances which is decidedly rare. There are, however, at least 14 recorded cases of multiple exostoses in which there was a single pelvic growth causing obstruction, with a fatal result in 10. In addition, some 30 cases of an isolated osteochondroma of the pelvis causing obstruction to labour have been recorded, with fatal results in 13.—I am, etc.,

Department of Applied Statistics, University College, London, April 25th. PERCY STOCKS.

ACTIVATED FLUORESCEIN IN THE TREATMENT OF CANCER

SIR,—Since the publication of Dr. S. Monckton Copeman's latest article on the use of "activated" fluorescein in cases of cancer, which appeared in the *British Medical Journal* of April 18th (p. 658), he has received letters of inquiry from radiologists in various parts of the country as regards the details of the technique. Therefore we have decided that it would be advisable that I, as the radiologist responsible for the practical side of the work since the earliest case was first attempted at St. Mary's Infirmary, Islington, and subsequently for all the cases at the Royal Northern Hospital, should state as concisely as possible the full details at present employed at this hospital, and, incidentally, in my private practice as well.

In the past, unsuccessful cases have come to our notice in which the radiologist has adopted a technique which has varied more or less from the one I personally have found to produce the best results. I wish to make it perfectly clear that I am not necessarily using the ideal procedure—this will be the subject, we hope, of future scientific investigation—but surely it is unfair to blame this method for these unsuccessful results when employing a different technique from the one which I have found so far to be of the most practical value. For instance, apart from the use of a different filter, it has been found that too great a concentration of fluorescein, particularly on the skin, not only fails to produce the required result, but also gives rise to a slight *x*-ray erythema. Also the preparation used must be alkaline, and not neutral. Here follows the technique.

Dosage, 6H; filter, 4 mm. of aluminium; spark-gap (between points), 7 inches; kilovoltage, 110; milliamperage, 4. Time taken, from 10 to 15 minutes. Three weekly doses are given, followed by three weeks' rest. This cycle is then repeated for at least six months, and then occasional doses are given up to a year or longer. This dosage, except in a few cases in which the fluorescein solution was too concentrated (that is, more than doubled), has so far produced no signs of erythema. Details of application are as follows:

1. For painting on the skin.—Sodium fluorescein 2.5 per cent., sodium bicarbonate 3 per cent., glycerin 2 per cent., in distilled water.

2. For oral administration.—Capsules of sodium fluorescein 1 gram to 3. Administer half to one hour before treatment.

3. As a "swallow."—Sodium fluorescein 5 per cent., sodium bicarbonate 3 per cent., glycerin 2 per cent. This "swallow" is used for growths in the pharynx, etc., when impossible to spray.

4. *Intravenous injection for lung cases.*—Sodium fluorescein 5 per cent., sodium bicarbonate 3 per cent., in normal saline. Use 20 c.cm. and inject fairly slowly—say, three minutes. This has no toxic effects. Treat immediately after injection.

5. Injection of nodules.—Same as for painting.

6. Bladder injection.—Sodium fluorescein 2.5 per cent., potassium fluorescein 2.5 per cent., sodium bicarbonate 3 per cent., in normal saline. Leave for ten minutes and then remove, leaving about four ounces.

7. Enema.—Same as bladder injection. Decant as much as possible.

The rest of the technique is the same as for ordinary *x*-ray treatment—that is, either direct or cross-fire radiation may be used.—I am, etc.,

London, W.1, April 26th. CLAUDE GOULDESBROUGH, Medical Officer in Charge, X-ray Department, Royal Northern Hospital.

VACCINE DOSAGE

SIR,—The main reason for the extreme divergence may be that given by Dr. Shera—the divorce of the clinician from the pathologist. The latter has perhaps insufficient material on which to test out his products and also his theories of the immunity mechanism. But there must be other reasons if good results can be claimed from such markedly differing doses as Dr. Balme has been advised to use. If a vaccine is non-specific, then large doses are undoubtedly necessary, and one must suspect that where doses of from 200 to 400 million are advised any effect produced by the vaccines of that pathologist are due to protein content. The presumption is that either T.A.B., or even milk, would do as well. It is true that specific vaccine may be *tolerated* in large doses, but reaction will follow *small* doses, which is not the case with the non-specific. The size of the dose of a specific streptococcus vaccine recommended by the pathologist will depend largely on the effect he hopes to produce. Should he look for a solid blood immunity, he will suggest large and increasing doses—more or less regardless of slight reaction. On the other hand, he may believe, as I do, that reactions are harmful, and should be avoided; then small, and often diminishing, doses will be advised.

Taking the actual numbers quoted by Dr. Balme: bacteriologists will agree that roughly 1,000 million

streptococci dried weigh one milligram. The dose recommended is therefore from 0.2 to 0.4 mg. If, in a case of tuberculosis, a pathologist were to suggest 0.2 to 0.4 mg. of T.B.E. as an initial dose, he would probably be deemed to be a criminal lunatic.

It is agreed that in all vaccine treatment, *ceteris paribus*, the dose is inversely proportionate to the area or total volume of the disease. In a fairly generalized case of rheumatism it will be conceded that the extent of the disease is much larger than in a case of phthisis. Therefore the dose of streptococci in rheumatism should be relatively smaller than that in tuberculosis. At the present day nobody would recommend an initial dose of T.B.E. larger than one ten-thousandth part of a milligram. This is the equivalent of 100,000 streptococci. If, then, definitely specific streptococci are injected in a fairly severe case of rheumatism, on general principles one would expect the comparable initial dose to be somewhere below one-tenth of a million, depending on the extent of the disease.

There is, however, a point in the technique of preparation which may affect the potency of the vaccine. The longer certain streptococci are cultured in the laboratory, the less virulent do they become for rabbits. Even after two or three subcultures an arthritis easily induced by a fresh culture no longer appears. Probably we may assume some difference also in the antigenic properties of streptococci thus treated. It seems, then, that autogenous vaccines of streptococci should be made from freshly isolated microbes. Again, most pathologists make their primary culture on ordinary blood agar. This is a poor medium for the non-haemolytic streptococci. Non-pathogenic varieties are much more likely to grow than pathogenic. Here, possibly, is the explanation of the non-specific character of so many streptococcal vaccines. But supposing the streptococci to be actually of the correct type, the number of subcultures may well account for a difference between a dose of 100,000 and a million or 10 million.

Finally, those who have a considerable experience of vaccine treatment will bear me out in the statement that, because a given dose x provokes a reaction, it does not follow that $10x$, or even $100x$, will have a proportionately larger effect, or even any effect at all. It appears that over the whole scale of possible dosage there is a more or less narrow range where the vaccine produces a reaction. Those doses outside this range, either below it or above it, may produce no reaction and no effect whatever. A most striking instance occurred recently in my own experience when a patient, who had been having 500 million streptococci once a fortnight without effect of any kind, suffered a severe reaction after a dose of a tenth of a million of the same vaccine diluted down. In order to obtain a standardization of dosage it is necessary, first, to find some test for specificity (for example, the so-called blood pathogen-selective test might help here); then to standardize methods of culture; and, finally, to decide on the *method* of dosage which gives the best results.—I am, etc.,

London, W 1, April 27th. H. WARREN CROWE.

POST-ENCEPHALITIS

SIR,—In a leading article in the *Journal* of April 25th on post-encephalitis and its problems you refer to the use of my influenza antigen in the treatment of bad behaviour cases. The antigen I supplied to Dr. Hill was made from the sputum of a typical case of influenza, and since it produced focal reactions in the brains of his patients it has a special significance in connexion with the etiology of the disease. One really ought not to speak of post-encephalitic conditions, for in these cases the encephalitis has never ceased to exist, and is progressive. It is very significant that practically every encephalitic is a carrier of influenza bacilli, which can be isolated from the naso-pharynx. This enables the antigen to be made from the patient's own strain, which is very desirable. As soon as the case is diagnosed this ought to be done and immunization started. If it is, there is every reasonable prospect of permanent recovery. Even when Parkinsonism has supervened it is possible to obtain arrest and slow recovery in some cases, but if early specific immunization is used Parkinsonism does not occur.—I am, etc.,

University College, Dublin, April 27th. W. M. CROFTON.

CORONARY THROMBOSIS AND MYOCARDIAL INFARCTION, WITH GLYCOSURIA

SIR,—A case of the above is described in the *Journal* of April 11th (p. 618) by Dr. Norman Cruickshank. The author mentions that a combination of coronary thrombosis and glycosuria is now becoming recognized as a definite syndrome. It is important to appreciate, however, that while only an infinitesimal proportion of diabetics exhibit thrombosis of the coronary arteries, some 25 per cent. of patients with coronary thrombosis suffer, or have suffered, from hyperglycaemia. The distinction is necessary.

In summarizing his case, Dr. Cruickshank considers it more probable that the glycosuria and coronary thrombosis "result from a common cause (vascular degeneration) than that glycosuria is an etiological factor in the production of coronary thrombosis." The conclusion is perfectly sound; but it is more than surprising that, in spite of the blood Wassermann test upon this patient yielding a positive result, a syphilitic etiology to account for the coronary thrombosis, the infarction, and the glycosuria, was neither considered nor acted upon. The reason for this is apparently to be found in the fact that, even in this present day, so much clinical and pathological diagnosis is based upon the pre-treponemal, pre-serological, and gross naked-eye criteria of syphilis. It seems in this case that the modern pathology of syphilis—upon which both accurate diagnosis and adequate treatment must be based—was not taken into consideration. The failure to realize the syphilitic causal factor is due, of course, to an unfamiliarity with the histo-pathological work of Warthin and all that it implies. Where the clinical concept is determined by an obsolete pathological picture, then the causal part played by syphilis is, more often than not, unappreciated. It does not yet seem to be generally realized that syphilis is, first, last, and all the time—even before the appearance of the chancre—essentially a disease of the cardio-vascular system. Every sign and symptom, from the alpha of the initial sclerosis to the omega of general paresis, is but a manifestation, varying according to age, intensity, and site, of a perivascular infiltration of lymphocytes and plasma cells evoked in response to the presence of the *Treponema pallidum*. This is the "vascular degeneration" to which Dr. Cruickshank refers.

A coronary thrombosis, a myocarditis, a condition of heart-block, especially in the absence of the Stokes-Adams syndrome, or a glycosuria are individually signs for the performance of a Wassermann test. Any one of these conditions cries out for a careful historical, clinical, and serological investigation as to the presence of syphilis. When found in combination, these symptom-complexes change suspicion into virtual certainty, and in spite of a negative blood Wassermann examination. Where the serology is negative, if the full provocative procedure is carried out—a blood test every twenty-four hours for seven days after the injection of an arsenobenzene compound, and then again on the twelfth and fourteenth days—a positive result is often obtained. In those who

still remain negative under this, the proportion who show at necropsy histological evidence of syphilis is so high as to explain the value of the therapeutic test.

The post-mortem cardio-vascular findings in Dr. Cruickshank's case pointed definitely to syphilis, even though they were only naked-eye in character—advanced aortitis, infarction of anterior wall of left ventricle above the apex, and an atheroma of the coronary arteries. I remarked in the *Journal* of April 26th, 1930 (p. 798), with reference to a paper by Dr. Crichton Bramwell on coronary occlusion, that a myocarditis is the commonest visceral lesion in syphilis, and that its most usual site is on the anterior wall of the left ventricle just above the apex. This myocarditis resolves itself into a cellular infiltration—progressing to a fibrosis—of the terminal branches of, usually, the left coronary artery. A progressive and ascending gradual occlusion of this vessel takes place, and the end-result is an anaemic necrosis (white infarct). The condition is, in short, a consequence of syphilitic myocarditis. This was the condition found in Dr. Cruickshank's case.

It is true that Levine finds only 4.5 per cent. of his cases of coronary thrombosis to be syphilitic, but then his criteria—post mortem at any rate—for the presence of syphilis are not sufficiently searching. He also finds, however, that the relationship between this condition and glycosuria was present in 23.7 instances. He feels that "among the distinct disease entities that are etiologically related to coronary thrombosis, diabetes is second in importance only to a previously existing hypertension." It is upon this that Dr. Cruickshank rightly joins issue with him in these words: "It seems more probable that the two conditions result from atheromatous changes in the coronary and pancreatic vessels respectively. It is difficult to imagine how glycosuria *per se* could determine the onset of coronary thrombosis." What both writers overlook is the frequency with which syphilis is the cause of myocarditis, atheroma, hypertension, and glycosuria.

The relationship of diabetes to syphilis is much closer than is usually considered to be the case. Post mortem, it is found that a combined interlobular and interacinar pancreatitis with atrophy of the islands of Langerhans, is practically always present in cases of late syphilis. It is usually localized and patchy. It appears that the form of pancreatitis most frequently associated with diabetes is due to syphilis; but at the same time it must be said that severe degrees of this pancreatic involvement may exist without the occurrence of glycosuria. In this connexion is to be borne in mind how often glycosuria is associated with neurosyphilis—in some 10 per cent. of paretics. It is therefore probably true that the pancreatic changes are not the sole factors causing the development of glycosuria, but that there must be taken into account similar changes in the liver, suprarenals, and in the brain.

It is unfortunate that the necropsy on Dr. Cruickshank's case was not carried out in detail—that is, the staining of sections from the myocardium and pancreas for treponemata by the Warthin-Starry silver-starch-gelatin method. Without this, the pathological diagnosis is incomplete. It would be very valuable, but admittedly laborious, if pathologists in investigating cases for syphilis would section and stain tissues from heart, aorta, pancreas, suprarenals, and testes for the cellular perivascular specific picture and for the parasite itself. The post-mortem diagnosis of syphilis is microscopical.

An extensive bibliography of syphilis of the pancreas will be found in an article by Wile in the *Archives of Dermatology and Syphilology* (1921, iii, 122); and some additional recent references are given by Berghausen in the *American Journal of Syphilis* (1930, xiv, 71).—I am, etc.,

Municipal Clinic, Salford, April 13th. E. TYTLER BURKE.

THE POST-INFLUENZAL COUGH

SIR,—Dr. G. Richardson's useful contribution to our knowledge of this common and most distressing sequela (April 18th, p. 685) tempts me to join issue with him on one small point only. He maintains that "the whole extensive group of morphine-heroin remedies spoil the appetite and practically do no good at all." My rejoinder would be: "That depends on how they are administered." I would much like him to give a fair trial to the following prescription, which was designed, or at least modified, by the late Sir Felix Semon in the 'nineties, and always gave him satisfaction in the treatment of such cases. In any case, I think it would be a pity if it were entirely forgotten.

Morphine hydrochlor., 3/4 grain.
Apomorphine hydrochlor., 1/2 grain.
Acid hydrochlor. dil., 10 minims.
Syrupi fici., 4 drachms.
Syrupi pruni. virg., 2 drachms.
Aq. dest. to 6 oz.
One to two teaspoonfuls every hour until the cough abates.

Sir Felix Semon believed that the good results he obtained were due to the biologically antagonistic action of morphine and apomorphine. Whatever the mode of action, the mixture is most pleasant to take, quite harmless in view of the almost homoeopathic quantities of the contained drugs, and, as I have often proved to myself and others, of the greatest value in all cases of spasmodic cough.—I am, etc.,

London, April 21st. HENRY C. SEMON, M.D.

SIR,—We must all admire Dr. Richardson's clinical account of the post-influenzal cough; but I venture to disagree with him as to its causation, and consequently as to its treatment. I attribute the cough to a pharyngitis, and not to a tracheitis—a pharyngitis which is sometimes accompanied by a relaxed uvula. My treatment is therefore directed to the throat, and I find that painting the throat five times a day with glycerin of tannic acid promptly stops the cough. The last painting of the day should be done half an hour before bedtime. As an alternative, a sedative spray may be used, but it must be used frequently.—I am, etc.,

King's Heath, Birmingham, April 20th. W. A. MARRIS.

THE MODERN CONCEPTION OF EARLY PHTHISIS

SIR,—Dr. H. V. Morlock's valuable paper (*British Medical Journal*, April 25th) explains once more the fallacies of the pre-*x*-ray doctrine, according to which phthisis was supposed to begin at the apex of the lung. He thus confirms my results published nineteen years ago. Dr. Morlock, however, attributes the "new" teaching to papers published in 1924-28, and especially to a book published in Germany in 1929, whereas my own description was published in 1912 (Peribronchial Phthisis, *Practitioner*, February, and *British Medical Journal*, August 31st). These papers of mine were fully illustrated; they aroused lively discussion at the time, and I believed they had produced a permanent change in view regarding the onset and course of pulmonary tuberculosis. A recent short paper by me on the same subject appeared in the *Franco-British Medical Review* for June, 1930. If the work of Redecher and others (referred to by Dr. Morlock) was entirely independent of my earlier observations, that, of course, accentuates its value.—I am, etc.,

ALFRED C. JORDAN, M.D., M.R.C.S., D.M.R.E.

London, W.1, April 25th.

DIAGNOSIS AND TREATMENT OF SUBPHRENIC ABSCESS

SIR,—Within the last few months two instructive papers have been published in the *British Medical Journal* on the diagnosis and treatment of subphrenic abscess. Both authors comment on the fact that the *x*-ray examination has not proved of much help in the diagnosis. The *x*-ray evidence relied upon is simply that there is an elevation of the affected side of the diaphragm due to a localized bulging thereof, accompanied by restricted movement. Sometimes there is in addition a gas bubble within the abscess cavity.

When I approached the subject as clinical assistant in the *x*-ray department of the London Hospital, I quickly realized how inadequate was the *x*-ray evidence alluded to above. After careful thought I decided that the best method of approaching the subject was to rely upon screen technique, and not films.

Subphrenic abscess is an uncommon disease, and few radiologists see many cases. At the Miller General Hospital for South-East London, during the past six years only nine or ten patients have been admitted with this condition. Of these, two or three were not *x*-rayed, and all died. The diagnosis was made at operation or post-mortem examination. Of the six or seven cases I saw, I was able to make the correct diagnosis in every instance, for each one was operated upon. Of this group all but one were simple cases—that is, uncomplicated by an empyema. These simple cases all survived except one, where the physician found himself unable to reconcile the physical signs with the *x*-ray report. Having the spirit of conviction, he kept the case under observation for a fortnight. The patient was now gravely ill, and was sent back to me for re-examination. I could only report the subphrenic abscess still present and much larger. Surgical treatment was promptly applied, and a large subphrenic abscess opened, but the patient succumbed. The single complicated case was a right-sided subphrenic abscess with a right basal empyema; but even here I was able to recognize both abscesses.

Space does not permit a description of my technique, because diagrams are necessary. I rely entirely on the screen examination of the diaphragm, noting its position, shape, and especially the nature of its movements. It is essential to use hard rays when dealing with a combined subphrenic abscess and adjacent empyema. The localization of the abscess by screening is a comparatively simple matter. Examination of the case sheets during this period shows that no genuine case of subphrenic abscess has been overlooked by the *x*-ray department, though mistakes have been made in suspecting it where it was not present. It is important to note, however, that the physician always has the temperature chart and the blood count to help him.

These results justify me in my belief that the *x*-ray examination can be made a most reliable method for diagnosing and localizing this important condition.—I am, etc.,

London, W 1, April 27th JOHN R. WYLIE.

PRIMARY TREATMENT OF CARBOLIC ACID POISONING

SIR,—My short article on carbolic acid was primarily intended to draw attention to the immediate treatment of the poisoning from the simplest standpoint possible; for my own and admittedly limited experience—of other men's efforts—has shown that the subject is worthy of attention. Mr. Bowdler's letter (April 18th, p. 686) in this connexion may therefore be considered a good result of this effort, since his valuable experience might otherwise have been lost. One cannot help feeling that if Mr. Bowdler had given a summary of his cases, with special reference to the circumstances under which they occurred—one of the most important facts to be considered in the treatment of any poisoning—his letter would have gained still more in value; especially as it would appear that his results were obtained under works conditions in which prompt attention should be available, and very different from telephoned cases of accident or attempted suicide several miles away from the doctor. I find myself a little puzzled to understand why Mr. Bowdler, while strongly agreeing in principle with me in the external treatment, denies its possible value to soothe and limit absorption from other surfaces, especially when he again agrees with me in regarding the use of sulphates to limit absorption as an essential part of his treatment; unless, which is surely unlikely, he still assumes the old and erroneous theory that inorganic sulphates assist in the metabolism of the absorbed carbolic acid.

In this connexion I would draw attention to the interesting example of a treatment being introduced into medicine on an entirely wrong basis, subjected consequently to much adverse, hostile, and even bitter criticism, found valuable by the experience of obstinate clinicians, and eventually explained by more recent scientific work; for such is the history of the use of sulphates in carbolic acid poisoning. Potassium chlorate in throat affections is another example of this type, though as yet the explanation of its beneficial value is undiscovered. The lesson seems to be that neither the laboratory nor the clinic should waste too much time and effort in upholding a hypothesis, but that both should strenuously endeavour to substantiate the facts. Bearing this in mind, therefore, one may willingly accept Mr. Bowdler's choice of castor oil, since he has not only had experience of its use, but also because this oil has a higher partition coefficient for the acid. A study of various oils would probably show that even better ones exist, which might be made available in places where accidents are likely to occur. Fundamentally an inert oil with a high affinity for the acid is the ideal. The suggested use of paraffin was made in order to focus attention on the fact that other commonly available oils are decomposed into absorbable constituents in the intestine, and thus there is a theoretical objection on these grounds. Actually, however, provided that this point is realized and precautions are taken to prevent its occurrence (by the free use of sulphates), castor oil or olive oil would probably be better than paraffin. I cannot agree with Mr. Bowdler that the suggested dose falls into that strange, old-fashioned group called "heroic"; a stomach must be very damaged indeed to be unable to hold half a pint of an inert oil, and if so damaged it would certainly be heroic for both the patient and the doctor to attempt to wash it out. That the oil should "embarrass the absorbing glands," which Mr. Bowdler suggests as an objectionable possibility, seems a most unreasonable criticism.

The emphasis placed by Mr. Bowdler on the wash-out method thoroughly carried out with plain water, and his general objections to using the stomach as a sort of test tube in which to neutralize poisons, is standard teaching, though regrettably not eliminated from all the textbooks. In cases, however, of corrosive poisoning, this treatment has fallen into disrepute except in those cases in which it is applied immediately. May I point out that no wash-out affects the intestine, from which much of the absorption will take place; and may I repeat that oil does not invalidate the use of the wash-out? In certain cases in which very prompt remedies may be used, and especially in those in which the poison has been taken shortly after food, or is

in some relatively insoluble form (certain sheep dips, etc.), emesis and an immediate wash-out is certainly indicated. It may, however, be remembered that, following the administration of such powerful local anaesthetics as carbolic acid, vomiting is difficult or impossible to produce. Finally, may I say that I do not wish either Mr. Bowdler or anyone to imagine that I believe there is one certain, simple, and best way to treat every case of any condition whatever. In the practice of medicine the best results are always obtained by the use of that fine discrimination which is frequently, cynically, optimistically called common sense.—I am, etc.,

O. S. GIBBS.

London, W.8, April 21st.

HALLUX VALGUS

SIR,—At long last the general hospital surgeon is waking up to the fact that excision of the head of the first metatarsal is a bad operation for hallux valgus, and judging from the progress made by the orthopaedic surgeon he will probably be doing likewise in a few more years.

Twenty-five years ago a lady asked me if I could relieve her of a deformity which was wounding her vanity. She had hallux valgus. I excised the head of the first metatarsal. The aesthetic result was all that could be desired, but her power of walking was considerably impaired.

The next case I had was in a bricklayer. The same operation and the same result; only it was more unfortunate in the bricklayer's case, as he had to stand and walk about all day to earn his living. However, I had learnt my lesson.

My third case was not for hallux valgus, but for a much more crippling condition—namely, hallux rigidus. In this case I removed the base of the first phalanx and part of the shaft, also a ridge of osteophytes around the upper margin of the head of the first metatarsal. The result was so satisfactory, both to the patient and myself, that I have never varied the procedure since, either for hallux valgus or hallux rigidus.

Why teachers and authors of textbooks persist in recommending excision of the head of the metatarsal is only understandable for two reasons: either they are carrying on the traditions of former writers, or else they never see the after-results of their operations.—I am, etc.,

J. STEWART.

Leeds, April 21st.

THIRTY-EIGHT YEARS WITH A FRACTURED SPINE

SIR,—The unusual length of the period of survival after sustaining a fracture of the spine seems of sufficient interest to warrant forwarding the particulars to you for publication. Perhaps some of your readers can answer my contention that the case is unique. During my student days it was generally thought that the maximum expectation of life after such an injury was two years, while the average was much shorter. Only recently I treated another man who lived over twelve years, after being thrown from his horse and sustaining a fracture of the spine through the twelfth dorsal vertebra. The present case was somewhat similar.

On August 8th, 1892, a telephone linesman, aged 21, fell from a high telephone pole and fractured his spine between the eleventh and twelfth dorsal vertebrae. After a stay in hospital, he was sent home, and was attended by my predecessors in this practice. On my first making his acquaintance, just ten years ago, he was living in a spinal carriage, with complete paralysis of both legs and lower abdominal muscles. Contraction of the muscles had taken place, with the result that the legs were stiff, the hips being in normal relation to the body in the supine position, the knees extended, and the ankles and feet in extreme talipes equino-varus, with large corns over the external malleoli from friction of the bedclothes. Nursing was carried on by his sister, some eight or nine years older than himself; no bed sores appeared in the whole period he was under my observation. Naturally he had incontinence of urine and faeces, and suffered from cystitis. He washed out his bladder daily with a weak solution of Condy's fluid, using an ingenious siphon arrangement attached to an ordinary rubber catheter. Twelve months ago a perinephritic abscess appeared in the right loin. This was incised without the necessity of an anaesthetic, and later discharged urine and pus through a small sinus, urine also draining per urethram. Death finally ensued on March 9th, 1931, through renal insufficiency due to pyelonephritis secondary to cystitis, the man then having just passed his sixtieth birthday.

I shall be glad to hear from any of your readers who are interested in this class of case.—I am, etc.,

DOUGLAS GREEN.

Sheffield, April 21st.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

Mr. Snowden introduced the Budget in the House of Commons on April 27th. He did not announce any general change in the rates of income tax, but proposed that on assessments under Schedules B, D, and E three-quarters of the tax due for 1931–32 should be payable on January 1st, 1932, and one-quarter on July 1st, 1932. This applies to the tax on salaries and professional earnings. Mr. Snowden proposed no new taxation, except an increase of 2d. a gallon on the petrol duty. No abatement was indicated for petrol used by *medical men*, nor any change in the taxation of motor cars. The proprietary medicine duty remains unaltered.

Discussion of the Budget proposals occupied the House of Commons on the following days.

On April 24th the House of Commons passed the Workmen's Compensation Bill through the report stage and third reading. The Solicitor-General, Sir Stafford Cripps, said the Bill would carry out the true intention of Parliament in the Act of 1923. The Bevan *v.* Nixon's Navigation Company judgement would no longer be applicable. Mr. Rowson explained that this was the case of a man certified to be suffering from miner's nystagmus. The Bill concerned the compensation of partially disabled men.

On April 27th the Parliamentary Medical Committee met. It was announced that the Minister of Health had intimated that he felt unable to appoint an advisory committee in rheumatic diseases. The committee was informed that the Proprietary Medicines Bill would be introduced very soon, probably by Mr. Somerville Hastings. The Pharmacy and Poisons Bill was then discussed, and an arrangement made for Mr. H. N. Linstead, secretary of the Pharmaceutical Society, to address the Medical Committee on the subject at the next meeting on May 12th. The committee may ask to meet the Minister in charge of the Bill. At a later meeting of the committee Sir Leonard Hill will speak on the ventilation of the House of Commons.

Voluntary Hospitals and Approved Societies

DR. FREMANTLE asked Mr. Greenwood, on April 23rd, what was the approximate estimated cost of services rendered by voluntary hospitals to members of approved societies. Mr. GREENWOOD said that no material was available for such estimate. Dr. FREMANTLE asked what contributions were made by approved societies to the funds of voluntary hospitals in return for services to their members. Mr. GREENWOOD said the total amount allocated by societies in England in payments to hospitals under schemes consequent upon the second valuation was about £300,000 per annum. Schemes based on the third valuation were in operation in societies covering about one-quarter of the total insured population. Under these latter schemes the annual amount allocated to hospital benefit had been increased about 14 per cent. above that previously allocated. Dr. FREMANTLE then drew the attention of Mr. Greenwood to the fact that last year University College Hospital treated over 2,000 members of approved

societies at a cost of £22,000, towards which the societies contributed little more than £3,000, and that of 124 such societies whose members were admitted to the hospital, 44 contributed part of the cost and 80 contributed nothing. Dr. Fremantle asked the Minister to bring the claims of voluntary hospitals to the notice of approved societies when allocating their disposable surpluses. He wished to know whether Mr. Greenwood could not draw the attention of the societies to the fact, which they probably did not realize, that they were getting much more from the voluntary hospitals than was covered by the small contributions which they made. Mr. GREENWOOD replied that the attention of all approved societies had been directed to provisions of the National Health Insurance Act, under which they were empowered to allocate part of any disposable surplus disclosed on valuation to the making of payments to hospitals in respect of the maintenance and treatment of their members therein. He was prepared to do what he could in the matter, but had no power to enforce contributions.

Pharmacy and Poisons Bill

REPORT STAGE IN THE LORDS

On April 27th the House of Lords considered the Pharmacy and Poisons Bill in the report stage.

On Clause 18 (prohibitions and regulations with respect to the sale of poisons) Lord PHILLIMORE moved an amendment providing that, subject to the provisions of Part II of the Bill, it should not be lawful for any person to keep open shop for the dispensing of prescribed medicines unless that person was an authorized seller of poisons.

Lord PONSONBY, who was in charge of the Bill, opposed the amendment, which, he said, would have the effect of preventing anyone except a registered pharmacist making up a prescription of a medical practitioner. It was a proposal of a very far-reaching character. The Government had consulted members of the medical profession, and had their wholehearted support in opposing the amendment. Those who supported the amendment were asking for pharmaceutical chemists an absolute monopoly. The amendment would rule out Army dispensers, those holding certificates of the Society of Apothecaries, and all unregistered dispensers. Whether that should be done or not he did not wish to argue on that occasion. It was quite obvious, however, that if such a drastic proposal were to be adopted and put into an Act of Parliament a widespread inquiry into the whole question must first be held. For these reasons he could not alter the attitude which he took up on the amendment when it was moved in the committee stage.

The amendment was negatived.

A number of other amendments, mostly of a drafting character, were agreed to, and the report stage was concluded.

National Insurance

Mr. GREENWOOD told Mr. Remer, on April 23rd, that at the close of 1930 £127,000,000 stood at the credit of National Health Insurance Funds in Great Britain. These funds were required in respect of future liabilities. He added that on March 31st, 1931, £46,000,000 was in hand in the funds under the Widows', Orphans', and Old Age Contributory Pensions Acts.

Sale of Milk

Mr. GREENWOOD, answering Mr. Butler on April 23rd, said that, in consultation with Dr. Addison, he was considering a proposal made by the standing committee of agriculture for England on the laws relating to the sale of milk.

Mr. OSWALD LEWIS asked Mr. Greenwood whether he would promote legislation to prohibit the importation or sale of milk preparations not containing a prescribed minimum of milk fat. Mr. GREENWOOD said he knew that such legislation existed in other countries, but he did not think it necessary in the interests of public health to introduce it in this country. He was not satisfied that there was a lower standard in this country than abroad.

Dental Benefit.—On April 20th Mr. GREENWOOD told Mr. R. J. Russell that the number of insured persons in England and Wales eligible in 1930 to receive dental benefit was approximately 10,500,000. Of these, the number who received the benefit was believed to be rather over 1,000,000. The cost of the benefit to approved societies in 1930 was roughly £2,100,000.

Darwin's House.—Replying to Mr. Freeman on April 22nd, Mr. SHORT said Down House, Downe, Kent, was not registered, and no licence for experiments to be performed on animals there had been granted under the Act. He could not say whether it was intended to use these buildings for the purposes of experiments on animals.

Dead Infants in Hong-Kong Streets.—Dr. DRUMMOND SHIELS told Mr. Graham White, on April 22nd, that of 1,851 dead bodies of children of 3 years of age and less picked up in the streets of Hong-Kong during 1928, in no case was there found to be any evidence of violence. In 521 cases of children of 3 years or under the cause of death was found to be small-pox.

Physical Condition of Recruits.—Mr. GREENWOOD, in reply to Mr. Tinker on April 23rd, said the Ministry of Health had obtained full information from the War Office regarding the physical disabilities which caused the rejection of 52 per cent. of men offering themselves for the Army from October, 1929, to September, 1930. This information would receive his careful consideration. Lord WINTERTON asked if Mr. Greenwood had seen a manifesto issued by a number of doctors who asserted that this low physical condition, and deficiencies in health and teeth, were due in part to the artificial foods eaten in this country. He asked if that report would be considered by appropriate experts in the Ministry of Health. Mr. GREENWOOD indicated assent.

The Factory Act: Medical Service.—In reply, on April 23rd, to Mr. Somerville Hastings, Mr. SHORT said the only whole-time official appointments of medical officers in the factory service were those of the medical inspectors of factories, who now numbered eight. Certifying and other surgeons appointed under the Factory Act for particular duties numbered about 1,800, and held part-time posts. In 1929, the last year for which figures were available, 5,531,322 persons were employed in factories, including 347,480 outside workers.

Animal Pathology Research.—Dr. ADDISON, answering Mr. Lees on April 23rd, said he was aware of the financial difficulties of the Animal Pathology Research Institute attached to the Royal Veterinary College at Camden Town. He trusted that a scheme upon a considerable scale for the development of research of animal diseases would be sanctioned and brought into operation at no distant date. This scheme was in an advanced state of preparation. Dr. FREMANTLE asked if an opportunity would be given to the House of Commons to discuss this scheme. Dr. ADDISON asked for notice of this question.

Vaccination.—On April 27th Mr. GREENWOOD gave Mr. Freeman a statement showing the number of public vaccinations and revaccinations, and the number of deaths from small-pox, in each of the ten years from 1920 to 1929. For the year ended September 30th, 1929, there were 258,996 successful primary vaccinations and 12,898 successful revaccinations, while the deaths from small-pox for the whole of 1929 were 30. In 1921 the figures were: successful primary vaccinations 245,154, revaccinations 26,775, and deaths from small-pox 5. In 1919-20 the total expenditure of local authorities on vaccination was £133,265, and the cost of the Government lymph establishment £11,973. In 1923-24 the total expenditure was £235,677, and the cost of the lymph establishment £16,553. In 1928-29 the total expenditure was £191,643, and the cost of the lymph establishment £15,377. Of the total cost of the Government lymph establishment, 15 to 20 per cent. each year was attributable to the cost of lymph supplied to the Service departments.

Rheumatism.—On April 23rd, in an answer to Mr. White, Mr. GREENWOOD said that after careful consideration he had decided that he would not be justified at present in setting up an advisory committee on rheumatism on the same lines as the advisory committee on cancer.

Radium.—In answer to Captain Peter Macdonald, Mr. GREENWOOD said, on April 23rd, that he understood the National Radium Trust would take into consideration the reported discovery of radium supplies in Canada as a source of supply for British hospitals.

Obituary

JAMES LORRAIN SMITH, M.A., M.D., LL.D., D.Sc.

F.R.C.P.Ed., F.R.S., F.R.S.Ed.

Professor of Pathology and Dean of the Faculty of Medicine, Edinburgh University

James Lorrain Smith, who died in Edinburgh on April 18th, was born on August 21st, 1862, the fourth son of the late Rev. Walter Smith, Half Morton, Dumfriesshire. He was educated at George Watson's College, Edinburgh, and at Edinburgh University. He graduated M.A. in 1884 with first-class honours in philosophy, winning the Vans Dunlop Scholarship in Philosophy and the Ferguson Scholarship in Philosophy. He then took up the study of medicine, but there is no doubt that his early philosophical studies exerted a profound and lasting influence throughout his life. He graduated M.B. C.M. in 1889 with first-class honours. After serving as resident under Dr. (later Sir James) Affleck in the Royal Infirmary of Edinburgh he proceeded to Oxford University, where he worked and taught under Professor Burdon-Sanderson. There he became closely associated with Dr. J. S. Haldane, and collaborated with him in an important series of physiological studies on the respiratory functions and the oxygen capacity of the blood. At that time he seemed destined for a career in physiology, but in 1892 he went to Cambridge as John Lucas Walker Scholar under Professor Roy, and while extending his physiological researches entered on his life's work as a pathologist. In 1893 he graduated M.D., and was awarded a gold medal for his thesis on "Thyroidectomy and respiratory exchange—a contribution to the pathology of myxoedema."

In 1895 Lorrain Smith was appointed lecturer on pathology in Queen's College, Belfast, and honorary pathologist to the Royal Victoria Hospital. He was remarkably successful in his academic work in Belfast, and there he first attained professorial rank. In 1904 he was appointed to the chair of pathology in Manchester University. After eight years of distinguished service in Manchester University he was appointed in 1912 to the chair of pathology in Edinburgh on the retirement of Professor Greenfield. He thus returned to his own school after a mature experience as a teacher and investigator. In 1909 he was elected a Fellow of the Royal Society of London in recognition of his scientific work. During the war Lorrain Smith devoted his attention to the problem of wound sepsis, and with his assistants devised the well-known hypochlorite solution ("eusol") which was so extensively used at that time in the treatment of septic wounds. In Edinburgh he developed his method of teaching morbid anatomy, which he had inaugurated in Manchester. This was based on a correlation of the clinical and pathological findings in individual cases of disease. Cases were chosen representing the fundamentals of pathology. The student was supplied with notes of the clinical history and with naked-eye and microscopical specimens, which were studied in detail under the tuition of demonstrators. A full report, describing, discussing, and correlating the clinical and pathological findings, was then submitted to the teaching staff for criticism. In this way the student was introduced to a real correlation of pathology and the clinical aspect of disease, which involved a study of pathology from the broadest point of view. This system proved highly successful, and became a notable feature of the undergraduate study in Edinburgh.

In 1919 Lorrain Smith was unanimously elected dean of the Medical Faculty, and continued to hold this office up to the time of his death. It is significant of the high appreciation in which he was held by his colleagues that when in 1930 he expressed a wish to resign this position, he was pressed to continue in office, and special arrangements were made to assist him in his administrative work. In January, 1931, he showed signs of a serious lesion, and an acute complication developed. After a palliative operation his general condition improved for a time, and he was able to devote the last two months of his life to reading and writing on a subject near to his heart—the history of his own native parish in the Borders. His death came almost unexpectedly from a recrudescence of the previous complication.

His more important scientific work included a series of studies on the physiology and pathology of the respiratory functions; the oxygen capacity of the blood; the determination of blood volume; carbon monoxide poisoning; the metabolism of fat in its physiological and pathological relationships; the microscopical identification of lipoids; the definition of lymph capillaries in the tissues; and the antiseptic properties of hypochlorous acid. On these and other subjects he published a considerable number of papers, mostly in the *Journal of Physiology* and the *Journal of Pathology*. During the last few years his interests were centred mainly in the study of the tissue lymph capillaries, and quite recently he introduced an original method for their demonstration. During the last two years he was absorbed in the writing of a monograph on "Growth," which embodied the work and thoughts of his whole scientific career. In 1922 he received from Belfast University the honorary degree of LL.D., and last year the University of Manchester showed its appreciation of his academic and scientific work by conferring on him the honorary degree of D.Sc.

He took part in various Government inquiries, and in 1901 was a member of the Royal Commission on Irish University Education. He was also a member of Home Office committees on humidity in cotton-weaving sheds and flax mills, and conducted for the Home Office inquiries into the pathological effects of factory conditions among workers in the spinning industries. As professor of

pathology in the University he held the office of honorary pathologist to the Edinburgh Royal Infirmary, and was consulting pathologist to other institutions in Edinburgh. He took a keen interest in comparative pathology, and was chairman of the research committee of the Animal Diseases Research Association of Scotland. He represented Manchester University in 1912-13 on the General Medical Council, and again joined the Council in 1927 as representative of Edinburgh University. Professor Lorrain Smith was vice-president of the Section of Pathology when the British Medical Association held its Annual Meeting at Oxford in 1904, and president of the Section of Pathology and Bacteriology at the Annual Meetings at Cambridge in 1920 and Edinburgh in 1928. In 1894 he married Isabella, daughter of Ebenezer Edmond, I.C.S. He is survived by his wife, a son, and four daughters.

Throughout his life Lorrain Smith retained a philosophic outlook and a breadth of vision which impressed all with whom he came into contact. To him pathology was no isolated subject, but was a phase of disordered physiology, and medicine as a whole, a branch of the wider science of biology.

In the three universities which he served Lorrain Smith was a leader of academic life, and showed great qualities of academic statesmanship. Though he was always reluctant to express himself in public, he nevertheless exercised a great influence in university affairs. A few years ago he was successful, with the co-operation of several professorial colleagues, in co-ordinating the whole teaching of the third year of medicine into practically a unified course—a notable achievement in medical education, which illustrates his capacities in leadership. His ideal, also, was to establish a similar co-ordination of the earlier biological studies of the medical students so as to link up closely their work in botany, zoology, physiology, and anatomy. He was one of the most lovable of men, considerate of others to the utmost degree, calm and unhurried in judgement, and a constant source of inspiration to his fellow men.

T. J. M. AND S. S.

Sir ROBERT PHILIP sends the following appreciation:

By the death of James Lorrain Smith an eminent authority has passed from the sphere of medicine and a vital force from the University of Edinburgh. His passing was peaceful, as was his life. One of his last requests was that there should be no garlands and no mourning. It is good that we respect his wish and let him rest quietly like a soldier at the edge of the battlefield, reverently recalling him in his strength—his intellectual vigour, his wide scholarship, his scientific ardour, his fine humanity, and his genius for friendship. *Justus et tenax propositi*: such is the epitaph which occurs to me as, with a sense of loneliness—*desideriis ictus fidelibus*—I sit and think of my dear friend of many years. Just balance in judgement and unflinching determination when his judgement was formed. Whether it was a scientific problem or an administrative question, the same principle governed his thought and action. He asked for facts and time to think all round the subject. Patient—curious even—in seeking evidence, he was open to approach from every side. Once his judgement was formed, he stuck to it with imperturbable firmness.

Lorrain Smith was fortunate in his upbringing and training. It is given to few to combine so admirably the scientific and the philosophic outlook. He was at home in the laboratory and in the academy alike. Medical problems were viewed by him from every angle. He revelled in the recent *rapprochement* between science and philosophy. He could not abide artificial division or limitation. His earlier work in the field of physiology led him naturally towards the interpretation of the abnormal. If formally he was labelled a pathologist, he remained a biologist in thought and work. Behind the simple microscopical field he visualized filaments linking the cellular process under review with the wider problems of life which floated unceasingly before his imagination. The living cell—physiological or pathological—was for him the key to many of the secrets of medicine. "Where others hear but a hum and see but a beam, the tongue and eye of the fountain of life he knew." He realized the harmony of life and disease, ever listening for the deeper chord. Incessantly he mused on the mysteries of growth. "If only there were more time," he would say; "if only there were more time!" As he thought, so he taught. While insisting on exactness in immediate observation by the unaided eye or under the microscope, he sought to lead the student's mind from the fixed product of disease back through the chain of events to the earliest departure from the normal. His students learned to link the end-result with the train of incidents which the clinical history and observation had revealed, or might have been made to reveal. Pathology was to be interpreted in terms of physiology.

His strong sense of the value of co-ordination led to one of the latest developments in the medical curriculum at Edinburgh. The professor's constructive mind realized the immense significance to the young student, who had completed the subjects of anatomy and physiology, of having his introduction to the phenomena of disease unified and at the same time made simple and comprehensive. In collaboration with his professorial colleagues, and with the authority of the Faculty, Lorrain Smith got the subjects of the third year—namely, pathology, pharmacology and therapeutics, junior medicine and junior surgery—intimately linked, so that, in place of an imperfect patchwork stitched together by the tyro himself, the varying occurrences in the course and progress of disease were unfolded to him in natural sequence. The results have been abundantly evident in the remarkable awakening of interest and in the higher quality of work in the clinical wards and at the final examinations. This reward was a great source of gratification to Lorrain Smith up to the last.

His qualities of head and heart were recognized by his professorial colleagues alike in medicine and in other departments. On the retirement of Professor Harvey Littlejohn, Lorrain Smith was invited to occupy the chair as dean of the Faculty of Medicine. His occupancy of the post was conspicuously happy. His intellectual gifts and sympathetic personality won for him readily the confidence and affection of his colleagues. His wide knowledge and administrative outlook ensured that the multifarious and responsible affairs of the medical side of the University were dealt with in statesmanlike fashion. In every matter he gave—and asked for—clear consideration of the issue, and a decision justified by the facts. On questions where there was doubt or reasonable difference of opinion he never failed in generosity. The place of honour accorded to him by the Faculty was amply realized and appreciated by the Senate.

Sympathetic towards all men, Lorrain Smith was an ideal friend. His family, and those who were privileged with his confidence, knew what a warm heart beat below the calm, apparently impassive, exterior. Naturally independent himself, he sought to foster independence in those he loved. Yet in times of difficulty, as when sickness or misfortune brought dependence, no one could be more wise or kind in extending the helpful arm. He helped many over the stile. The great gathering at the memorial service in the Senate Hall was a remarkable tribute to the respect and affection in which Lorrain Smith was held by his friends, his peers, and his pupils alike.

Professor MUIR (Glasgow) writes:

For me it is both a duty and a privilege to write something about Lorrain Smith, one of my oldest and most intimate friends. During a friendship of over forty years my regard for him and my admiration of his powers have steadily grown. He has given service of permanent value to the three universities in which he worked and taught, and has left a deep impress on his own science; above all, his personality made him a power in his several spheres of work. It is rare that one so gifted in philosophy should devote himself to medicine. We cannot say what was the determining factor in his so doing, but there is no doubt that the work of his choice was thoroughly congenial to him. The scientific problems of medicine specially appealed to him and the desire to investigate gradually grew. His philosophic training gave him the power to correlate the results of various sciences as few can do and to take a comprehensive view of scientific truth as a whole.

He learned physiology, notably that of metabolism, from Noël Paton, and pathology, especially in its morphological aspects, from Greenfield; and he early conceived the idea of linking the functional and structural changes in disease more closely together—of applying the methods of physiology to pathological problems. With a view to a fuller equipment in these methods he proceeded, shortly after graduation, to Oxford to study under Burdon-Sanderson, by whom he was greatly influenced. He was there fortunate in becoming associated also with John Haldane in his work on respiration and allied subjects. At Oxford and later at Cambridge he carried on his investigations in this particular field and he continued them when he went to Belfast. They deal with such subjects as the physiological effects of breathing vitiated air, the effects of oxygen at high tension, the mass and oxygen capacity of the blood, etc.; they all constitute advances in particular directions and their fine quality has been generally recognized. The work in this department which is best known to pathologists, however, is that in which he applied the carbonic oxide method to the determination of the blood volume in cases of disease and which led to the demonstration that in various forms of anaemia, especially that of chlorotic type, the volume of the blood is markedly increased.

During his tenure of the chair of pathology at Manchester two events were of special importance in connexion with his scientific work. In the first place, he took up the equipment of the pathological museum and the preparation of a catalogue, and this step led to his method of mounting together organs from the same case, this in its turn leading to his now well-known "case method" of teaching pathology, which has been a feature of the Edinburgh school during his occupancy of the chair. In the second place, it was in Manchester that he made his first observations on fatty degeneration. This subject became for him one of far-reaching importance; and, one question leading to another, the outcome was a series of papers continued during his tenure of the chair at Edinburgh, which taken as a whole constitute a contribution to pathology of outstanding importance. New and valuable methods were introduced by him and have taken a permanent place in pathological technique, but like Weigert he devised each not as a technical achievement but for the determination of some particular point at issue. His work in this domain was continued to the end and two recent examples of it may be mentioned. One is that in which he showed that the earliest changes in cloudy swelling and in fatty degeneration occurred in the mitochondria, and the other in which he demonstrated that the distribution of lymphatics in the liver could be defined as the result of autolytic changes. Both of these investigations, as well as several others, were carried out in association with his colleague Dr. Rettie. Whilst we have referred to his work in these two chief spheres, it must not be overlooked that at Belfast he published also papers on bacteriological subjects and on sewage; at Edinburgh during the war he carried out investigations on the pathology of trench foot and also on antiseptics for purposes of wound treatment, the outcome of which was the well-known "eusol."

It will be seen that Lorrain Smith's investigations were in diverse fields. In all of these he gave us something new, something suggestive and leading to further inquiry. I have already referred to the quality of his work; it has been characterized by breadth of view and by imagination, and it has stood the test of further inquiry. In fact, his papers have essentially advanced or modified our views; they have been real contributions to knowledge. It is somewhat remarkable that while his original work dealt mainly with general and experimental problems, no one recognized more fully or insisted more strongly on the importance of morbid anatomy in the teaching of pathology. He looked on it as the sure and firm basis to which all disturbances of function are to be related. The thorough working out of the pathology of individual cases had in his view more practical and educational value than much reading. And the general could always be illustrated from the particular. His endeavour was to give his students a true scientific interest in the problems which they were subsequently to face, and on this was based his method of teaching. His view of his science was a comprehensive one, and while the great and fundamental problems specially had his interest, the teaching of pathology had equally his care. It is a fact of interest, however, that his earlier researches were more of physiological type, or, rather, were carried out by the methods of physiology, whilst those of later date were largely histological and microchemical; but it was simply a case of using the methods necessary for a particular problem, while function and structure formed for him parts of one whole.

No one could come into contact with Lorrain Smith without being impressed by his personality. His intellectual powers were of unusual order and this was apparent in the discussion of any subject. His knowledge of physiology affected his manner of viewing the problems of biology, and one could not fail to learn and get new points of view from him on any subject discussed. His interest in philosophy never waned, and formed the basis of many friendships, but in literature also and especially in poetry he was widely read and had a fine critical perception. His mental powers had a counterpart in his largeness of heart. His was a character of unusual sincerity and simplicity. He could take enjoyment from the small as well as from the big things of life and he brought to his contemplation of them a full sense of humour. By both temperament and training he had the philosophic outlook and a rare power of estimating the real value of things. He was kindly, thoughtful of others and helpful, and his generous nature was shown in what he expected from others as much as in what he gave. He worked earnestly and resolutely for any cause which appealed to him and in such work his personal interests seemed to be forgotten. In fact I may say that I have known no one less self-centred than he or further detached from personal ambition. His qualities were seen in his dealings with his students and colleagues alike, while the feeling he inspired in his friends was nothing less than devotion.

Professor A. MURRAY DRENNAN (Queen's University, Belfast) writes:

In 1912 Professor Lorrain Smith succeeded Professor Greenfield in the chair of pathology at Edinburgh, and so I gained a new chief and commenced a friendship which

continued till his death. His first procedure on coming to the laboratory was characteristic of him ; he came among us smoking his pipe, seated himself on a laboratory stool, and chatted about what we were doing. He then outlined the general course of teaching work we would carry out, and finally suggested that he would like to demonstrate in my practical class. It was a new and disturbing thought that one's chief should be one's demonstrator, but after the first meeting it seemed the most natural thing in the world, for he was there to help and not to criticize. Soon after his advent to Edinburgh he began to introduce the case system of teaching pathology, and it was my privilege to work with him day after day preparing the illustrative cases which formed the basis of the system. It was a great pleasure and a great inspiration, for the labour was lightened by his genial good humour, and was made increasingly interesting by the problems that constantly cropped up in almost every case. We kept a list of these in the hope of having, in time, a worker for each problem, but it would have needed an army! When the war came he tackled what was one of the early problems—a cheap but efficient antiseptic first-aid dressing, especially one to combat gas-gangrene organisms. The result was a hypochlorite powder, which we called "eupad" for short (a contraction for *E*dinburgh *U*niversity *P*athological *D*epartment!). Later a solution of this was used and christened "eusol" (*E*dinburgh *U*niversity *SOL*ution). He was intensely interested in the practical effects of these, and he went to the out-patient departments of the hospitals and personally inspected the results of dressings from day to day. But one might repeat the same story under various titles ; whether it were war wounds, trench feet, or lipoid metabolism, he was always helpful, interested, and enthusiastic, and he had the great faculty of making all of us who worked with him equally enthusiastic. He was indeed our Chief, but a kindly, beneficent chief who cheered us on while working with us, who gave us sound advice, and who, when work was put aside, was ready to enjoy a round of golf with the same enthusiasm and good humour as he exhibited over a pathological problem. After I had gone to New Zealand we regularly corresponded, and I looked forward with the greatest pleasure to his long letters. They were full of new work in hand or new ideas that had occurred to him, garnished with amusing comments. He was always pleased to hear what one was doing, and was helpful in his criticisms. He will remain for me—as he must for all who had the privilege of working with him—the ideal chief, the true friend, a kindly elder brother.

J. FARQUHAR CHRISTIE, M.B., F.R.C.P.ED.

Lecturer on Skin and Venereal Diseases, University of Aberdeen

The death of Dr. John Farquhar Christie, which occurred on April 14th, came as a shock to the medical community, as it was not generally realized how seriously ill he was. His passing leaves a blank in the profession in Aberdeen which will not be readily filled.

Dr. Christie was educated at Aberdeen Grammar School, from which he passed to the University. He graduated M.A. in 1891 and M.B., C.M. in 1895. He then became a resident in the Royal Infirmary, working in the wards of Dr. Blaikie Smith and Dr. R. J. Garden. The latter was at that time lecturer in skin diseases, and no doubt it was the stimulus of his teaching which early turned Dr. Christie's mind towards dermatology, as when he went to Germany later he occupied his time there mainly in the study of skin diseases in Bonn, Leipzig, and Berlin. After a period as assistant, he returned to Aberdeen and started in general practice. In 1898 he was appointed clinical registrar at the Royal Infirmary, in 1901 lecturer on diseases of the skin to the University, and in 1903 was put in charge of the department of skin diseases in the Royal Infirmary in the post of assistant physician ; in 1910 his status became full physician. His professional success was rapid, and in a comparatively short time he had possibly the best private practice in Aberdeen of the last quarter of a century.

During his school and university days he took a keen interest in cricket, and captained both the school and the university clubs ; later, when in practice, he continued his active participation in the game with such zest that during the seasons 1907–8–9 he captained the Aberdeenshire cricket club, which during this whole period were Scottish champions. Christie was regarded as an inspiring captain, and undoubtedly one of the most popular figures cricket has known in the North-East of Scotland.

He was a member of the British Medical Association, and for several years acted as honorary secretary of the Aberdeen, Banff, and Kincardine Branch, to which he gave valuable service. He was a member of the Central Council in 1918–19, an honorary secretary of the Section of Dermatology and Syphilology at the Annual Meeting at Aberdeen in 1914, and president of the Section of Dermatology at Newcastle-upon-Tyne in 1921.

For many years he took an active interest in the Volunteer movement, and at the outbreak of the war was a major in the R.A.M.C.(T.) attached to the 4th Battalion Gordon Highlanders, but was not mobilized owing to his being seriously ill with diphtheria. Later he acted as honorary consulting dermatologist to the Aberdeen military hospitals from June, 1915, to December, 1918. Soon after the war he gave up general practice and devoted himself entirely to his specialty, combining with it the direction of the venereal disease department at the Royal Infirmary. In the year 1926–27 he was president of the Aberdeen Medico-Chirurgical Society.

In accomplishing what he did, particularly in general practice, he owed much to his extraordinary energy and business method. He attached his patients to him as much by his devotion to duty and sympathetic handling as by his undoubted ability and skill. He was an acute clinical observer, of keen deductive faculty, and as a lecturer he was always lucid and interesting. These qualities, and his social gifts and hospitality, made him popular with his students, and still more so with his residents, in whom he always took a real and helpful interest. As a colleague he was loyal and genuine, with a great capacity for friendship, very frank and outspoken when he thought there was need, but always without bitterness or rancour. He leaves a widow and daughter, whose unexpected sorrow is deeply shared by all his colleagues and a host of patients and students.

THE LATE MR. H. P. DEAN

Sir ARTHUR KEITH writes:

In the *British Medical Journal* of April 25th (p. 730) there is an announcement of the death of Henry Percy Dean at the age of 66, with a brief record of his career. If he had fulfilled the promise which we who were associated with him at the London Hospital thirty-five years ago perceived, he would have died the leading surgeon of his time. At the period to which I refer the London Hospital had taken him to its heart. Bringing him from University College, the London Hospital made him surgical registrar and then assistant surgeon. When he linked his fortunes to that of the London Hospital Sir Frederick Treves was at the height of his fame and power ;

he swayed the affairs of the medical school at every crisis. Presently the influence of Dean's personality—one of exceptional power—became felt. He quickly and quietly began to take the place which Sir Frederick Treves had occupied in hospital and in school. It was then, too, that Lord Knutsford came to the rescue of the London Hospital; his quick eye soon recognized the altogether exceptional abilities of Percy Dean, both as surgeon and as master of men. Dean at once set about reorganization of the medical school. It was he mainly that bought into the school Sir Leonard Hill, Sir Peter Chalmers Mitchell, Sir Henry Head, Dr. Robert Hutchison, Professor William Bulloch, and several others beside myself. He became the dominant spirit of the school for an altogether too brief period. He could organize; he not only gave everyone the impression he had great gifts—he possessed them. He had a most efficiently arranged mind; he reached his conclusions after due and deliberate consideration; having formed his judgements, he at once proceeded to impose them on public policy, pursuing the objectives he had in view without fear or favour. He was a born teacher; his thoughts were clearly cut; he laid them before his students with a conviction which can be born only of personal experience. In these early days he had established himself as an authority on the surgical treatment of sequelae which result from middle-ear disease. His contributions to surgery attracted the attention and won the approbation of the medical world. He could operate, and he was a clinician. Students sought his help in their troubles, and practitioners his advice and skill with their patients. He seemed destined to reap the highest rewards his profession could confer on its most distinguished votaries. What happened? I cannot tell. All I know is that some tragedy in his life robbed modern surgery of a man who, if things had been otherwise, would have left on its progress an enduring memorial.

Dr. THOMAS REDMAYNE, who died on April 1st at St. Leonards-on-Sea, was the younger son of Robert Robey Redmayne; he was born on June 20th, 1863, and from Repton went to Trinity College, Cambridge, completing his medical education at the London Hospital. He obtained the diploma of M.R.C.S. in 1886, the M.B. degree in 1888, and the Fellowship of the Royal College of Surgeons in 1889. After acting as receiving officer, house-physician, and house-surgeon at the London Hospital, Dr. Redmayne began practice at St. Leonards in 1890, going into partnership with Mr. Claude Baker Gabb. In 1896 he was appointed junior surgeon to the Royal East Sussex Hospital, and after a time became ear, nose, and throat specialist. On the administrative side of the hospital he served as a member of the house committee and as chairman of the medical committee. He was ultimately senior surgeon, retiring at the end of 1930, after thirty-four years' unbroken service. Dr. Redmayne had been a member of the British Medical Association since 1893. During the war he served for a year at the Netley Military Hospital. He had an important practice, to which he devoted most of his time; his advice was always valuable, and his opinions carefully expressed. A somewhat gruff exterior covered a kindly personality, and he was loved by his patients. For several years Dr. Redmayne was consulting surgeon to the Catherine House Home for Invalid Ladies, St. Leonards, and chairman of the Hastings Medico-Chirurgical Committee. He is survived by a widow and two daughters.

Dr. JAMES CAMPBELL HALL, who died on April 8th at his residence, Rowantree House, Monaghan, was for many years an outstanding member of the profession in Ulster. He was born at Kilkeel, County Down, in 1851, being the eldest son of the Rev. Richard A. Hall. After graduating M.B., B.Ch. at Trinity College, Dublin, in 1878, he became physician to County Monaghan Fever Hospital in the following year, and in 1890 he was appointed surgeon to the Monaghan County Infirmary, a post from which he recently resigned. Dr. Hall's life-work was the development of the county hospital, which was opened in 1896 largely through his perseverance. His devotion and generosity to this institution, with which he was associated for forty years, were commemorated in 1929, when a mural tablet, recording his services, was unveiled at the hospital. From the inhabitants of the county, by whom he was much beloved, he received an address and a presentation. In addition to his hospital work, Dr. Hall had an extensive private practice, and took a great interest in public affairs. In 1886 he contested unsuccessfully the constituency of North Monaghan as a Conservative candidate. He was a past-president of the Ulster Medical Society and of the County Monaghan Medical Association.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

In congregation on April 24th, Sir Humphry Rolleston, Bt., Regius Professor of Physic, was appointed the delegate from the University to the centenary of the School of Medicine of the University of Leeds on June 30th and July 1st.

At a congregation held on April 24th the following medical degrees were conferred:

M.D.—*H. V. Coverdale, G. K. Kirwan-Taylor.
M.B., B.CHIR.—M. A. Robertson, W. V. Howells, J. J. Keevil, I. B. Morris, J. A. Pocock.
M.B.—G. Rocyn-Jones.
B.CHIR.—G. K. Kirwan-Taylor

* By proxy.

UNIVERSITY OF LONDON

UNIVERSITY COLLEGE

The Bayliss-Starling memorial scholarship, of the annual value of about £120 (with exemption from tuition fees), is open for award by the University College Committee. The scholar will be required to follow a course of study approved by the Jodrell professor of physiology, involving a training in the principles of, and methods of research in, physiology and biochemistry. Applications, giving full particulars of academic career and qualifications, together with the names of three referees, must be sent by May 15th to Mr. C. O G. Douie, secretary, University College, Gower Street, W.C.1, from whom copies of the regulations can be obtained.

LONDON HOSPITAL MEDICAL COLLEGE

An open entrance scholarship, value £100, offered by the London Hospital Medical College has been awarded to G. E. Godber of New College, Oxford.

UNIVERSITY OF DUBLIN

TRINITY COLLEGE

At the first summer commencements in Trinity Term, held on April 24th, the following degrees in the Faculty of Medicine were conferred:

M.D.—H. O'D. Burke-Gaffney, J. V. Carroll.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

Six Hunterian Lectures on "Human monsters and malformations," illustrated by specimens, will be delivered in the theatre of the College by Sir Arthur Keith, M.D., F.R.S., on May 4th, 6th, 8th, 11th, 13th, and 15th. The first five lectures will be given at 5 p.m., and the last at 4 p.m.

Colonel Robert McCarrison, M.D., F.R.C.P., I.M.S., will give two lectures on "Experimental research at the Pasteur Institute, Coonoor, South India," on May 18th and 20th, at 5 p.m. The lectures will be illustrated by lantern slides and by specimens.

The subject selected for the Jacksonian prize for 1932 is "The pathology, diagnosis, and treatment of diverticula of the large and small intestine." Candidates must be Fellows or Members of the College, and essays must be received by December 31st, 1932. Full particulars can be obtained from the secretary.

Medical News

The Robert Jones Medal and Association Prize of the British Orthopaedic Association for 1930 has been awarded to Mr. Harold Clifford Edwards for his essay on "Injuries of the tendons and muscles."

The annual banquet of the Royal Medico-Psychological Association will be held in Dublin on Wednesday, July 8th, under the presidency of Dr. Richard Leeper.

A festival dinner in aid of the West London Hospital will be held at the Guildhall on May 12th, when H.R.H. Prince Arthur of Connaught will take the chair as president of the institution. On the afternoon of April 24th Prince Arthur visited the hospital and inspected the departments affected by the scheme of reconstruction and extension.

The annual general meeting of the Society for Relief of Widows and Orphans of Medical Men will be held at 11, Chandos Street, Cavendish Square, W., on Wednesday, May 13th.

A discussion on the relative value of induction of premature labour, test labour, and Caesarean section in the treatment of minor degrees of contracted pelvis will take place at the annual meeting of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine on Friday, May 15th, at 8 p.m.

Particulars of the lectures and demonstrations arranged for next week by the Fellowship of Medicine will be found in our Diary of Post-Graduate Courses, published in the *Supplement* at page 188. Several special courses have been arranged. Copies of syllabuses and tickets of admission can be obtained from the Fellowship, 1, Wimpole Street, W.1.

At a meeting of the National Institute of Industrial Psychology on Tuesday, May 12th, at 5.30 p.m., in the committee room of the Royal Automobile Club, Pall Mall, S.W., Dr. G. H. Miles, the director of the institute, will lecture on practical tests for drivers. This lecture is being held in connexion with the National Safety Week. The chair will be taken by the Hon. Sir Arthur Stanley.

An intensive post-graduate course in neurology and psychiatry will be held in Professor Wagner von Jauregg's Clinic, Vienna, from June 30th to July 31st. The pathology and treatment of the various nerve diseases will be dealt with fully, and special attention will also be paid to psychotherapy in its different aspects. The fee is 150 dollars U.S.A. (about £30), and payment may be made to the American Medical Association of Vienna, Alserstrasse 9, Vienna VIII, whence full details of the course may be obtained.

The following Friday evening discourses will be given this month at 9 o'clock at the Royal Institution (21, Albemarle Street, W.): May 8th, Dr. G. W. C. Kaye, superintendent of the physics department, National Physical Laboratory, on the measurement of noise; May 15th, Professor J. C. Philip, on experimental aspects of hydrogen-ion concentration; May 22nd, Sir William Bragg, on *x*-ray investigations of the structure of liquids; May 29th, Dean Inge, on the future of the human race.

An international conference on child welfare in Africa will be held at Geneva from June 22nd to 25th. The subscription is 15 Swiss francs. Further information can be obtained from the British Committee of the International Conference on African Children, c.o. Save the Children Fund, 26, Gordon Street, W.C.1.

The second biennial conference of the National Council for Mental Hygiene will be held from May 27th to 29th at the Central Hall, Westminster, and the subject of discussion will be the human factor as it affects international problems, crime, industry, the social services, and education. There will be afternoon and evening sessions, at 3 p.m. and 8.15 p.m. respectively. Delegates from societies and associations throughout Great Britain and from the Colonies have been appointed to the conference, and representatives from foreign organizations for mental hygiene are also expected to attend. Further particulars may be had from the secretary, 78, Chandos House, Palmer Street, S.W.1.

The fifth Congress of the French Societies of Oto-neuro-ophthalmology will be held in Paris from June 18th to 21st, with Professors Barré of Strasbourg, H. Roger of Marseilles, Portmann of Bordeaux, and Coppez of Brussels as presidents of honour, and Dr. Velter of Paris as president. The subject for discussion will be the oto-neuro-ophthalmological sequels of epidemic encephalitis, introduced by Drs. Portmann of Bordeaux, Riser and Méniel of Toulouse, and Teulières and Beauvieux of Bordeaux. Further information can be obtained from the general secretary, Dr. A. Tournay, Rue St. Lazare, Paris 9e.

The eighth International Congress of Photography, which was to have been held in Dresden in the last week of July next, has been postponed until August 3rd to 8th owing to the third International Radiological Congress being held in Paris at the former date. Further information can be obtained from Dr. R. Luther, Paradiesstrasse 2, Dresden-A-20.

An International Milk Congress will assemble in Copenhagen from May 14th to 17th, when a discussion will be held on the preparation of milk in different countries, with special reference to public health. Further information can be obtained from the secretary, International Milk Congress, 1931, Copenhagen.

A congress on nephrolithiasis will be held on May 24th and 25th at Vittel, when addresses will be given by Drs. Loeper, Vallery Radot, Labbé, Legueu, Abrami, van Leersum, and others. The subscription is 25 francs. The congress will be followed by a motor car excursion to the Vosges. Further information can be obtained from the general secretary, Dr. Maurice Boigey, Vittel.

The anniversary of Florence Nightingale's birthday, May 12th, is to be celebrated this year as Red Cross Day throughout the Empire. The April number of the *British Red Cross Society's Quarterly Review* is largely devoted to a study of her life.

Messrs. W. Heffer and Sons, Ltd., of Cambridge, have published for the Association of British Chemical Manufacturers, at the price of 2s., an *Index to Acts of Parliament and Statutory Rules and Orders affecting the Chemical Industry*, revised to the end of last year. The next list will be published early in 1932.

The issue of the *Zentralblatt für Gynäkologie* (No. 11*a*) is dedicated to Professor Walter Stoeckel, director of the women's clinic of Berlin University, on the occasion of his 60th birthday.

Strasbourg médical is this year celebrating the ninetieth anniversary of its foundation in 1841, when it was known as *Gazette médical de Strasbourg*, a title which it retained until 1914.

The King has granted to Major John C. Collins, R.A.M.C., licence and authority to wear the Insignia of Commander of the Order of the Nile conferred upon him by the King of Egypt in recognition of valuable services rendered.

Dr. W. Norwood East, Medical Commissioner of Prisons, has been appointed by the Home Secretary a member of the committee to inquire into existing methods of dealing with persistent offenders, and report what changes, if any, are desirable in the present law and administration.

The Brighton Town Council has ordered the preparation of plans for a sea-water swimming bath, medical baths, and a clinic for the treatment of rheumatism.

In the course of last year twenty-seven new Italian medical journals appeared and nineteen suspended publication. The largest output was presented by phthisiology, the journals dealing with this subject representing at least a quarter of all the new periodicals published in the course of the year.

We are asked by the Cure Commission at Hofgastein, Austria, to announce that their thermal baths will in future be available to qualified doctors and dentists free of cost. Members of these professions are exempted from the cure and music taxes, as are also their immediate relations, for whom special terms have been arranged.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM* 9861, 9862, 9863, and 9864 (internal) exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediscra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS

Dr. Christopher Woodhouse

"A. A. M." wishes to obtain particulars of the coat of arms of a certain Dr. Christopher Woodhouse, famous in his time for detecting witches, who lived in a house in Berkhamsted, and whose daughter was a great friend of William Penn.

Metal Water-taps and Fittings

"NEST" writes: I am considering a form of metal for use in a new clinic just erected by my authority, and it would be of great assistance to hear the experience of others with chromium-plated articles as to durability of plating. Is any other type preferred?

Psoriasis

"A. D." writes: I have a patient who is suffering from psoriasis, the situation being around the anus. So far, the usual forms of treatment have failed absolutely, or have given only temporary relief. I should be glad of any suggestions.

Foreign Ear, Nose, and Throat Clinics

"PERORAL" writes: I should be grateful for any information as to the opportunities for acquiring instruction and practice in laryngoscopy, bronchoscopy, and oesophagoscopy at one of the Continental centres, and advice as to the means of getting in touch with a teacher in these subjects.

Left-handedness in a Child

"M D." writes: A child of 4 is in the habit of feeding himself, though not very neatly, with his left hand. He can use his right hand equally well, but is not encouraged to do so by his mother, who has been told by a doctor that "his brain will not develop properly if he is encouraged to use his right hand." I should be obliged if someone with experience of bringing up left-handed children would advise me on this: Should the child not be allowed to use, and even be shown how to use, either hand for simple acts, such as feeding? What about games later? Must a child play ball games (cricket, golf, etc.) left-handedly if he is naturally left-handed? What literature is there on this subject?

Sour Milk

DR C. A. CORRAN (Kihikihi, New Zealand) writes in reply to the inquiry by "E. W. D.": My mother, who has had quite fifty years' experience in making this preparation for household use, gives me the following procedure (long in use by the people of Mount Lebanon). Heat fresh milk in a saucepan. Do not let it boil, but when on point of rising put aside for a few minutes to cool until lukewarm. To a portion of this add some "starter" (prepared by letting milk sour in the ordinary way, or reserved from a previous preparation). Add to the rest of the milk, stir well, and store in a stone jar or chinaware container. Cover well to keep warm, and set aside till next day. If made in the evening it should be ready for use about midday following. About three tablespoonfuls of "starter" are sufficient for a gallon of milk. Sometimes, depending on weather conditions, there will be a certain amount of water in it. If so, insert a spoon to side of jug and allow water to drain off. To make a white cheese from the above, fill a small muslin bag and hang up in a cool place for some hours until it no longer drips. Press out the remaining whey by leaving for a few hours beneath a suitable weight—for example, a domestic iron mortar. The cheese may be eaten sweet or salted. For three years past I have prepared excellent sour milk with a minimum of trouble by using an ice-chest. One simply takes fresh dairy milk, in pint glass containers, and stands these for some days in a cool box, kept at a low temperature (about 45° F.) by a small block of ice. It takes six or seven days to ripen; the curd is fine and flocculent, and the flavour rivals that prepared by the previous method. It is a more palatable addition to porridge than the conventional cream. In fact, the Lebanese have a very nourishing foodstuff called "khiskh," prepared by steeping finely ground whole wheat (previously boiled and sun dried) in soured milk, mixing the two intimately and drying in air and sun for two or three days until it is powdery, much resembling oatmeal in appearance. This preparation, stored away in jars or containers such as a tea caddy, remains fresh for months, and is a favourite and warming winter dish when cooked according to traditional custom.

Income Tax

Cash Basis : Change in Proprietorship

"BEWILDERED" was at one time in general and surgical practice on his own account. He then took another practitioner into partnership so far as the *general* practice was concerned, reserving the *surgical* practice to himself. Subsequent to the change the general practice and the surgical practice have been separately assessed on the basis of bookings, whereas, prior to that, the assessment (on the then combined practices) was based on cash takings. (*a*) Is the inspector of taxes correct in requiring "bookings" for the surgical practice, and (*b*) What is the position as regards cash received after the partnership in respect of work done during the sole proprietorship?

*** (*a*) Yes; the "bookings" basis is correct for both the present practices; (*b*) but on that understanding the cash receipts for work done prior to the partnership are not chargeable to income tax; they represent the collection of debts for work done in years for which "Bewildered" has accounted for income tax on adequate assessments of his earnings.

Obsolescence Allowance

"A. B. C." bought a new car in October, 1929, for £185, and for the financial year 1930-31 was allowed a sum of £37—that is, 20 per cent. of £185—for depreciation. In April, 1931, he sold the car for £115 and bought a new car of the same make for £190. What should he claim for 1932-33?

*** (*a*) Obsolescence allowance to be treated as an expense of the year 1931—that is, £185 − £37 − £115 = £33—and (*b*) depreciation allowance on the new car—that is, 20 per cent. on £190 = £38. It is possible that the Inspector of Taxes may object to the former allowance on the ground that the 1929 car was not "obsolete." If he does so, and if "A. B. C." does not think the point worth contesting, he might drop the obsolescence claim (though we do not advise it), and claim depreciation on £185 − £37 − £115 + £190—that is, £223 at 20 per cent. = £45; in the following year on £223 − £45 = £178, and so on, and in the long run the difference will not be substantial.

Professional Residence : Subletting

"DENSE" has a house which is assessed at £52 under Schedule A, and is used for resident patients as well as for general practice. A surgery is also sublet to a dentist for £120 per annum. Does the whole or any portion of this sum have to be returned for assessment, or can it be regarded as covered by the fact that the property is assessed under Schedule A?

*** The effect of a decision in a fairly recent case is that the subletting of a part of a property cannot be dealt with under Schedule D except as regards any special profit from providing furniture, services, etc. It would therefore seem that "Dense" is entitled to exclude the £120 from his professional receipts for purposes of assessment, but should make a separate return of that portion of it which represents any profit from providing cleaning or other services, etc.

Cost of Arranging New Partnership

"R. N. G." explains that a commission had to be paid by his firm for introducing a new partner in place of one who had died. Is this an admissible expense?

*** No. For one thing, it represents capital expenditure to cover a future period, and, for another, it is an expense incurred in connexion with the proprietorship of the practice rather than in carrying it on.

LETTERS, NOTES, ETC.

A Hospital Vacancy in Palestine

The Right Rev. RENNIE MACINNES, D.D., Bishop of Jerusalem, writes: Is there any medical man among your readers, or known to any of your readers, who would consider an invitation to take charge of St. Luke's Hospital, Hebron, in Palestine? This is a mission hospital, which is financed by the Jerusalem and the East Mission, and is the only hospital in this large Moslem town of 16,000 people. There is no other hospital within twenty miles, and there are many villages in the district which have no other place to turn to for treatment. The experience of the last eighteen months has shown that, in fact, village patients come in considerable numbers from a very wide area, sometimes walking two or three days to reach the hospital. Medical missionary work has been carried on in Hebron for thirty-eight years, before the war by the United Free Church of Scotland, and since the war by the Church of England. The hospital building is new, and has been brought up to date, with its own electric plant, etc., during the last few months, at an expenditure of some £3,500. There is an English sister as matron, and a competent native doctor and staff. The whole usefulness of the hospital is at present seriously limited by the lack of an English doctor. From the professional point of view the work would be most interesting, and it is essential that whoever offers should be a surgeon. There is no other missionary work at present possible in the town or neighbourhood, so that the opportunities before the hospital cannot be exaggerated. There is a chapel in the hospital building, and the grounds are large enough to permit of building a house for the doctor if suitable rented accommodation is not found. From the date that it was reopened, in September, 1929, just after the serious riots, the work of the hospital has received a great welcome from the people of the town, while relations with British Government officials have been most cordial. If any of your readers desire further particulars, would they communicate with my commissary, the Rev. E. M. Bickersteth, secretary of the Jerusalem and the East Mission, 12, Warwick Square, London, S.W.1?

Dislocation of Tonsil

Dr. H. J. MCCARTHY (Llandudno) writes: I was recently called to see a woman, aged 28, who was suffering from bronchitis. Later in the day I was sent for urgently, and was told that the patient had had a severe paroxysm of coughing, which had induced retching. At the end of this she had a lump in her throat, which made her feel as if she were choking. On examination I was astonished to find the right tonsil dislocated forwards from its bed. It was freely movable, and was attached only at its upper pole. It was swollen and oedematous when I first saw it, and twelve hours afterwards, when seen in hospital by some of my colleagues, it was plum-coloured. Under light anaesthesia it was a simple matter to remove it, and I found that the capsule had been torn, and that the major portion of enucleation had been performed by the patient's own efforts. Although I have made extensive inquiries, I have failed to find any record of a similar case, and should be interested to hear of any.

Pregnancy with Intact Hymen

Dr. J. SEFTON (Edgbaston, Birmingham) writes: The following case is of such medico-legal interest that it seems worthy of record. Mrs. X, aged 23, came to see me in April, 1930. She was married on December 26th, 1929. As far as I could ascertain from the dates, there had been three attempts at coitus: (*a*) between January 7th and 11th; (*b*) between February 16th and 23rd; (*c*) between March 16th and 23rd. The process was very painful to the patient, but at each attempt the husband emitted semen. On examination the hymen was found to be intact, having a small central perforation, which would barely admit the tip of the little finger. The membrane was thick and tough, and tender on pressure. The first day of the last period was March 8th, 1930, and as time went by, the diagnosis of pregnancy became certain. Save for proteinuria, between September 14th and November 1st, the pregnancy was uneventful. On January 19th, 1931, the patient was delivered of a normal male infant, weighing 6 lb. The hymen and perineum were torn (second degree tear). The puerperium was normal. The child was jaundiced for three days, but has since got on quite well. Since the sperm is said to die within a few hours of deposition in the vagina (unless it enters the cervix), this case illustrates the powerful forces which tend to direct the sperm on its path. Further, the child was scarcely up to the average size and weight, yet the minimum period from coitus to delivery was 302 days. I take it that either the size and weight of a child are no index to the length of its sojourn *in utero*, or else that the sperm existed in the genital tract for some weeks before fertilizing the ovum. The former seems unlikely, and the latter is the usually accepted view.

Puerperal Inversion of the Uterus

Dr. H. G. SWORN (Thorpe Bay, Essex) writes: Some years ago, when practising in Highbury, Islington, I was attending a patient in a private nursing home at Finsbury Park. The matron (a certified midwife) asked me to have a look at a lady in the home. She informed me that she had been confined about fourteen days previously; she was troubled because she could not feel the uterus, and the patient had a lot of haemorrhage. She had spoken to the doctor about it, and he did not think that there was anything to trouble about. I informed her that I could not see a patient of another doctor. The lady left the home at the end of the third week. The matron told her to call to see me, if the loss did not stop in a week. The patient came to my house after the week expired. On examination I found the inverted uterus in the vagina, so I sent her to the Soho Hospital. They were able to replace the uterus under chloroform. The interesting point about this case is that the patient was able to get about, and, apart from weakness from the haemorrhage, was in a fair condition.

Memorial to Joan of Arc

Miss BARBARA BARCLAY CARTER writes: May I beg the favour of your columns for an appeal to your readers to contribute to the English national memorial to St. Joan of Arc? Five hundred years ago this May she was burned alive in Rouen market-place, and now a small church is to be built to mark the spot, to which church it is hoped that England may provide the main doors, as *amende honorable* for her share in the death of the Maid. This memorial should have special interest for the medical profession. Two doctors were among the judges who condemned her, and it is to one of these, Master Tiphaine, who, when the case was reopened twenty years after, bore witness in her favour, that we owe precious details as to the conditions of her imprisonment. It is he who tells how, when she lay sick (yet still in chains) and he would have bled her, the Earl of Warwick intervened, crying that she might thus escape by death, which must not happen, "for she was a great prize for the King of England, who had paid dearly for her, and she must die by justice in the flames." Contributions should be sent to the honorary treasurer, Miss Sheila Kaye-Smith, c.o. St. Joan's Social and Political Alliance, 55, Berners Street, W.1. The names of all who contribute 5s. and upwards will be inscribed in a Golden Book, to be kept in perpetuity in St. Joan's Church.

Routes for Motorists

The information previously given by the Automobile Association in its itineraries is now augmented by the addition of detailed sketch maps, indicating not only the road to be followed, but also the adjacent country. These maps read in the direction of travel—from the bottom to the top of each page—and the itineraries are based upon a practical survey of the roads. The new map routes will be issued to members from all A.A. offices.

A blue-tinted petrol, containing a compound of lead and known as "B.P. Plus," is being put on the market by the British Petroleum Co., Ltd., at the ordinary price of petrol, and will shortly be obtainable from all "B.P." pumps.

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 48, 49, 50, 51, 52, 53, 56, and 57 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 54 and 55.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 187.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

412 Pernicious Anaemia Resistant to Liver Treatment

M. LABBÉ, R. BOULIN, PETRESCO, and SOULIÉ (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, February 16th, 1931, p. 217) report a case of pernicious anaemia which, apart from a transient rise of 4 per cent. in reticulocytes, failed to respond to treatment with liver or liver extract, although this was well tolerated, and was administered in doses equivalent to 260 grams of liver each day. The red cell count fell to 1,340,000 per c.mm., and the colour index rose to 1.53; the mean diameter of the erythrocytes was increased; the megalocytes numbered 7 per cent. and the white cells 3,400 per c.mm., but the latter increased to 13,000 with 71 per cent. polymorphs two days before death, when myelocytes and promyelocytes made their appearance. The tongue was smooth and red; there was complete achlorhydria; the patellar and Achilles reflexes were intact but feeble, and the other reflexes were normal. The urine contained abundant urobilin. At the post-mortem examination the bone marrow was described as very red. The authors consider that the patient died from the anaemia, and not from complications developed in the nervous system or from secondary infection, in spite of the raised temperature and the presence of pleural effusion.

413 An Outbreak of Trichinosis

F. C. ALDRIDGE (*Amer. Journ. Med. Sci.*, March, 1931, p. 312), who reports an outbreak in Pennsylvania, states that up to 1914 there had been recorded in the United States 1,550 cases of trichinosis, with 240 deaths, a mortality of 16 per cent. He suggests that the disease is much more prevalent, since the mild cases escape recognition. According to Blumer, 6 per cent. of American hogs have the disease. The outbreak described by Aldridge affected 29 persons, who were almost entirely of foreign birth, during a period of twenty-seven days. All except two were infected by pork from a single farm, where there was undoubtedly a local epidemic of the disease during the winter. Two patients died, 5 were acutely ill, 17 had mild attacks, and 5 had practically no symptoms. Characteristic eosinophilia was found in all except the two fatal cases. The principal clinical symptoms were facial oedema, muscular pains, headache, and fever. Treatment, except for initial purgation followed by an enema, was entirely symptomatic.

414 Pericarditis with Effusion

M. CHAVIGNY (*Paris Méd.*, February 28th, 1931, p. 204) points out that, more often than not, a pericardial effusion is posterior, and its diagnosis is difficult or impossible. He describes a case of a gunshot wound to the right of the sternum in the fourth intercostal space. A right haemothorax and an empyema supervened after three weeks, the latter being drained by operation. Eight days later the temperature rose rapidly to 104°; the heart sounds were not muffled, the apex beat was easily palpable, and dry pericarditis was diagnosed. The patient died of sudden heart failure twenty-four hours later, and at the necropsy there was found a pericardial effusion of about 800 c.cm. Chavigny recalls an earlier case in which he discovered 2 litres of pericardial effusion at the necropsy, though no signs had been apparent during life. Pulsus paradoxus had been noted; its presence led the author to have an *x*-ray investigation made in a later case, when a pericarditis with effusion was seen, though again all the classic signs were absent. Chavigny is unable to explain the mechanism of this sign in these cases, but suggests that its presence should at least indicate the necessity for *x*-ray examination. The only treatment that offers a possibility of cure is a pericardotomy. All his three patients treated in this manner made complete recoveries.

415 Meningococcal Meningitis in Infants

V. CANTALAMESSA (*La Pediatria*, March 1st, 1931, p. 234) records 42 cases of meningococcal meningitis in the first twelve months of life. In 22 the first symptoms were indefinite, consisting merely in irregular fever, restlessness, and vomiting, with frequent loose stools; in some there was only a slight constitutional disturbance. In 20 cases, however, or nearly 50 per cent., the onset was sudden, with high fever and severe constitutional disturbance, as in older children and in adults. This sudden onset was almost exclusively found in cases which had a rapid and particularly severe course in spite of the early application of specific treatment. A distinctly intermittent fever was specially noted in cases which ran a favourable though prolonged course. A moderate degree of splenomegaly was fairly frequent, and its presence was of diagnostic value in some cases.

416 Amylaceous Dyspepsia

L. J. PICTON (*Liverpool Med.-Chir. Journ.*, January, 1931, Part I, p. 36) incriminates starch as a primary cause of many cases of dyspepsia, and insists that bread, rice, and farinaceous foods generally may provoke anginal attacks and delay convalescence, in addition to causing gastritis in some circumstances. He remarks that when a diabetic patient is first placed on a starch-reduced diet, he is often agreeably surprised by the loss of a long-established dyspepsia, whereas the incautious eating of a starchy meal by a patient suffering from amylaceous dyspepsia may give rise to symptoms almost at once. Picton suggests that a working hypothesis to explain this and other phenomena of the kind is that there exists a regulator of the pace of the food through the alimentary canal; this is situated in the stomach, and becomes sensitized to starch, with a consequent reduction in the speed of passage of food and the originating of gastric retention. He adds that the incipient dyspeptic should have a dietary in which more greens and grilled meat replace the farinaceous components to a considerable extent, starchy food being restricted to separate meals. Salads contain 30 times less starch than an equal amount of bread, and afford the necessary bulk to the diet; the addition of fruit is a further improvement.

Surgery

417 Surgical Treatment of Bronchiectasis

C. A. HEDBLOM (*Surg., Gynecol. and Obstet.*, February 15th, 1931, p. 406) discusses the pathogenesis, diagnosis, and treatment of bronchiectasis, which may be unilateral or bilateral, congenital or acquired. In the congenital type, symptoms develop only after secondary infection, while the acquired type results from mechanical dilatation of bronchi weakened by infection. Atmospheric pressure in the presence of a subnormal intrapleural pressure may be the dilating force, or it may be the extrabronchial traction of fibrous scar tissue or a combination of both. This force can be completely neutralized by pulmonary collapse. The morbid process can be arrested by early diagnosis and prompt collapse, which not only prevents the dilatation from increasing, but also produces partial collapse of the dilated bronchi. In an incipient case early diagnosis is made possible by contrast media bronchography; compression treatment gives the best results. A positive contrast media bronchogram affords proof of the site, size, and type of the condition. Partial pulmonary collapse may be brought about by phrenic neurectomy, partial pneumothorax, or circumscribed thoracoplasty; pneumothorax or thoracoplasty will produce complete collapse. Phrenic neurectomy is the method of choice in early cases, and the best results

may be expected from compression treatment. Lobectomy, secondary to thoracoplasty, is safer than primary lobectomy, and is of use when the relief from thoracoplasty is insufficient. For cases with advanced extensive lesions, cautery extirpation and eradication brought about by mobilizing and prolonged contraction of the diseased lobe are alternative methods of treatment.

418 Ambulant Therapy in Proctology

G. SACKS (*Journ. Med. Assoc. of South Africa*, February 14th, 1931, p. 77) emphasizes the value of ambulant treatment in anal diseases. The injection treatment of internal haemorrhoids is in his opinion most valuable, and, except in cases of gross infection and bad prolapse, terminates very satisfactorily. He injects into the rectal submucosa a 5 per cent. solution of phenol in sweet almond oil, one inch or so below the last valve of Houston. The patient is so placed that the anal canal and lower rectum are inclined almost vertically downward, thus allowing air to distend the rectum. Four quadrants are injected at each sitting, 2.5 c.cm. being introduced into each quadrant. At weekly intervals four lower quadrants are injected, until the last injection is just above the haemorrhoids. This treatment is painless. Six or seven sittings may be necessary, but the number varies. The method does not depend on thrombosis, but on perivascular inflammation ending in fibrosis. In treating pruritus, diabetes and threadworms must be excluded, the rectum and anus be carefully examined, the diet be regulated, and cleanliness ensured. Subcutaneous injections may be tried, and silver nitrate solution be applied after anaesthetizing painful cracks and fissures with 10 per cent. cocaine. The skin turns brown, then exfoliates; when this is completed, calamine lotion is sufficient for cure. An operation is never necessary.

419 Treatment of Purulent Arthritis of the Knee

C. Willems some years ago advocated early movement of the joint in the treatment of septic arthritis, on the grounds that drainage was improved, better functional results were obtained, and atrophy of muscles was prevented. M. KAPPIS (*Zentralbl. f. Chir.*, March 7th, 1931, p. 579) has compared the results in 22 cases of septic knee-joints so treated, with 16 cases treated by drainage with immobilization during the acute stages. He finds that the functional results in the former series were definitely better, though the proportions of fatal cases, and of cases which eventually came to amputation, were about the same. The movements are induced as soon as puncture and lavage, or if necessary drainage by trocar or by incision, have been performed. If conducted sufficiently thoroughly, and the drainage is satisfactory, the movements should not be painful.

420 Hirschsprung's Disease

M. CHATON (*Bull. et Mém. Soc. Nat. de Chir.*, February 14th, 1931, p. 178) describes a case of Hirschsprung's disease in a man aged 21. Since birth he had suffered from obstinate constipation, and at the age of 11 an ileo-sigmoidostomy had been performed. When admitted to hospital ten years later he was suffering from complete intestinal obstruction; the bowels had not been opened for eleven days, and there was persistent vomiting. The abdomen was greatly distended, the respiration embarrassed, and the pulse rate 100. Radiography showed an enormous gaseous dilatation of the colon, which pressed against the diaphragm and caused the respiratory distress. An opaque enema stopped at the junction of the sigmoid and of the descending colon, which was also greatly distended. Operation through a McBurney's incision disclosed the large intestine considerably dilated, and an artificial anus was immediately made which allowed much gas and faeces to escape. The patient was instantly relieved, and the abdomen regained its normal size and appearance. Two months later the patient was in good general condition, but still showed some abdominal distension. An *x*-ray examination revealed that there was a condition of congenital megacolon combined with a reflux of faeces through the ileo-sigmoidostomy made ten years before. This had produced the symptoms of obstruction by general compression of the intestinal tract. Laparotomy was carried out and a huge megacolon was found. A complete colectomy was done and the operation was well borne, convalescence being uneventful. The patient subsequently left hospital in good health.

421 Staphylococcal Septicaemia

P. S. LOWENSTEIN (*Amer. Journ. Med. Sci.*, February, 1931, p. 196) illustrates the gravity of this condition by the fact that of 57 recently reported cases death occurred in 35, a mortality of 61.4 per cent. The prognosis is grave owing to the severe constitutional symptoms and the formation of multiple metastatic abscesses. The outlook is all the more serious if the focus cannot be removed or sterilized. Lowenstein recommends that blood cultures in suspected cases should be made at the earliest possible moment by a competent bacteriologist, and in the event of a negative result should be repeated at frequent intervals until bacteriaemia is ruled out. Although the value of staphylococcal antitoxin is still doubtful, it should be used in large doses intravenously, intramuscularly, and, if indicated, intraspinally. In chronic cases also staphylococcal vaccine is sometimes of value.

Therapeutics

422 Copper and Blood Formation

E. SCHIFF (*Med. Welt*, March 7th, 1931, p. 334) discusses the therapeutic uses of iron and copper in the treatment of anaemia. He refers to the observations of Steenbock and others that the readily soluble salts of iron ($FeSO_4$) are therapeutically more active than the less soluble salts (Fe_2O_3), but adds that these compounds become increasingly potent if the animal is also fed on fresh green vegetables or iron-free alcoholic extracts. Anaemic rats fed with high-grade refined iron salts remained anaemic, owing possibly to the removal of copper from the iron salts in the refining process. Copper is not comprised in the haemoglobin molecule, but all animal and vegetable cells contain copper. In milk there is about 0.06 mg. per cent., human milk containing about the same amount as cow's milk or goat's milk. The foetal liver contains about 1.97 mg. per cent., but there is less in the liver of the newly born, and in growing animals it has been shown that there is an increase of copper in the blood during pregnancy. It is suggested that the administration of copper together with iron, owing possibly to some catalytic action on the part of the copper, enables the therapeutic properties of the iron to become active.

423 Specific Hormone Treatment of Heart Disease

O. J. NIELSEN (*Ugeskrift for Laeger*, March 5th, 1931, p. 240) reports investigations on 47 patients suffering from various diseases of the heart; he treated them with lacarnol, an extract of heart muscle prepared by Bayer-Meister Lucius, and said to contain a cardiac hormone. The first therapeutic tests of this preparation were made some three or four years ago, when it was given by the mouth. Among the author's 47 patients were 18 suffering from true angina pectoris. Twelve of these patients derived so much benefit from this treatment that, since its institution, they had been completely free from attacks, the observation period being in no case less than three months. Three other patients, who had been subject to frequent attacks, suffered from them only occasionally, and the remaining three patients derived only transient improvement from the treatment. Of the 2 patients suffering from nervous angina pectoris, one improved under this treatment, which did not affect the other patient. Of the 4 patients suffering from deterioration of the myocardium without angina, two achieved marked improvement and one some improvement. The 2 patients suffering from arrhythmia perpetua derived some improvement, and of the 4 suffering from mitral disease, one showed marked and two some improvement. Among the 7 patients suffering from some neurosis of the heart

were four benefiting from the treatment. This was the case with three of the 8 patients suffering from high arterial blood pressure. Good results were also obtained *in 2 cases of encephalitis* with heart disease. The author finds it too early to be dogmatic about dosage, but his preliminary observations, which he finds encouraging, suggest that for severe forms of angina pectoris the following procedure is suitable. On the first day 1 c.cm. is given by intramuscular injection once or twice, and 15 to 20 drops three times by the mouth. On the following days the drug is given orally, its dosage being gradually reduced till only 5 to 10 drops are given two or three times a day. In no case did the drug cause signs of poisoning.

424 Gastric Tissue in Pernicious Anaemia

H. M. CONNER (*Journ. Amer. Med. Assoc.*, February 14th, 1931, p. 500) records the results obtained in 60 patients suffering from pernicious anaemia following treatment with extract of the gastric tissue of swine or with tripe. Two patients were given gastric tissue after tripe had failed, but tripe constituted the sole treatment given to two others. Forty-six cases were studied in hospital. The results with tripe are not included in this report as they were inconsistent and unconvincing, and were much inferior to those in cases treated with raw or dried gastric tissue. When the entire gastric wall was used, 240 to 480 grams were given daily, and half this amount when the mucosa only was administered. Raw and dry preparations yielded approximately equivalent results. The mucosa, the remainder of the stomach after removal of the mucosa, and whole gastric wall, were used separately; each proved effective. The presence of muscle was not required to obtain results in two cases treated with mucosa without the muscle coat or other muscle meat. Fundus and pylorus tissues, each used separately, produced satisfactory, if not equivalent, results. The effects on the reticulated and mature erythrocytes, haemoglobin and leucocytes, and also on the general and neurological symptoms, were similar and apparently equivalent to those obtained by liver or liver extract.

Radiology

425 Examination of the Fifth Lumbar Vertebra

H. HARTTUNG (*Zentralbl. f. Chir.*, February 21st, 1931, p. 453) remarks that owing to the change of curve from lumbar lordosis to sacral kyphosis, the fifth lumbar vertebra is particularly difficult to demonstrate clearly on a skiagram by the usual technique. By powerful flexion and abduction of the hips and flexion of the knees, the adoption almost of a lithotomy position, the lumbar lordosis can be eliminated and satisfactory skiagrams obtained. The position can be easily maintained by a girdle running behind the patient's neck, from one knee to the other. In a series of photographs the author illustrates the fact that many cases diagnosed as sacralized or otherwise abnormal lower lumbar vertebrae prove to be completely normal when photographed by the technique described.

426 Diagnosis of Tumours of the Small Intestine

T. S RAIFORD (*Radiology*, February, 1931, p. 253) discusses the diagnosis of tumours of the small intestine, with special reference to their *x*-ray appearances. A flat plate view of the abdomen is essential for comparison with plates from other directions, as well as to reveal the presence of large dense intra-abdominal masses. The barium meal is administered after this plate has been obtained, and half an hour later the plate for the duodenum is exposed. Subsequent plates are taken at intervals of four or eight hours, followed by a final 24-hour plate on the next day. A barium enema should be given at the end, in order to rule out involvement of the large intestine, and to reveal tumours near the ileo-caecal junction which press upon the caecum, causing a filling defect. All plates are taken with the patient standing up; if slightly over-exposed, the filling defects are more clearly brought out. From the radiological standpoint three sections of the small intestine are definable—namely, the duodenum, the jejunum and proximal ileum, and the terminal ileum. Raiford reports a series of 82 tumours of the small intestine, of which 39 showed *no* symptoms, and suggests a basis for the diagnosis of such conditions: by associating a complete *x*-ray examination of the whole gastro-intestinal tract with other investigations in doubtful cases, the radiologist will be able sometimes to give the patient the benefit of an early operation, or, conversely, to save him from a useless and discomforting laparotomy. This is particularly the case when a lesion of the duodenum is suspected; and another important indication for radiography is the possibility of the presence of non-obstructive growths in the abdominal cavity.

427 Radiography of Discrete Pulmonary Lesions

Commenting on the great diversity of techniques employed in pulmonary radiography, A. ZIMMERN and G. ARVANITAKIS (*Journ. de Radiol. et d'Électrol.*, January, 1931, p. 1) propose a uniform, systematized method which is specially applicable to discrete lesions and slight changes in the pulmonary parenchyma. Essentials for accurate diagnosis are a perfect definition, richness of details, and clearly defined contrasts. While certain factors cannot be standardized, such as the different types of apparatus used, some can be easily systematized. Among these are the position of the patient, the incidence of the rays, the anticathode distance, and the length of exposure. The apparatus should be placed against the thorax of the patient, who should be upright with arms crossed in front and with a forward rotation of the shoulder. This position clears the apices from clavicular shadows, and separates the scapulae. The radiograph should be taken in apnoea at the moment of inspiration. Brevity of exposure and correctness of the focal distance are the essentials of definition. The authors have found that one-tenth of a second is the maximum duration compatible with correct definition, and they propose that in adults an irradiation of 5 5/6 of the Benoist dose should be employed; this corresponds to a maximum of 65 kV. In children, according to their age and development, a lower tension (as low as 55 kV. for nurslings) should be used, and the exposure be shortened, since in the case of infants plates are easily over-exposed. The intensity employed depends on the type of apparatus.

Obstetrics and Gynaecology

428 The Female Sex Hormone in Pregnancy

G. L. KELLY (*Surg., Gynecol. and Obstet.*, March, 1931, p. 713) concludes, as the result of a series of experiments on guinea-pigs, that an excess of oestrin in the blood over the corpus luteum hormone is incompatible with conception and with the continuation of normal pregnancy. He found that the injection of small doses of oestrin into female guinea-pigs immediately after copulation prevented conception in all cases when the dose was adequate, the minimum dosage being 10 to 15 rat units. Moreover, interruption of pregnancy in this animal, when about two weeks advanced, could be effected in almost all cases by a dose of 100 rat units. Higher doses were similarly effective in later stages, but the maternal mortality rose rapidly. The death of the foetus after the injections seemed to be related to marked atrophic changes in the chorionic villi, resulting from pressure due to excessive hyperaemia or some other cause. The reason for the death of the mother was not discovered. The administration of oestrin in doses as high as 600 rat units to male and non-pregnant female guinea-pigs did not interfere in any way with their health and life.

429 Neo-natal Asphyxiation

Y. HENDERSON (*Journ. Amer. Med. Assoc.*, February 14th, 1931, p. 495) believes that the natural stimulus which initiates breathing in the normal child at birth is the carbon dioxide produced in its own body. The asphyxiated centre of the newly born, or of a drowned person, requires a much higher pressure of carbon dioxide than does a normal centre to stimulate it to respiratory activity. For such an asphyxiated newly born child dilatation of the lungs by a mixture containing a sufficient amount of carbon dioxide in oxygen to stimulate natural breathing is the one effective method of resuscitation. Inhalation of such a mixture is also equally important for many children who breathe spontaneously, for incomplete pulmonary dilatation is relatively common, and this predisposes to pneumonia, causing nearly as high a mortality as stillbirth itself. Henderson recommends such inhalation for all children in the first days of life as a precautionary measure against continuing partial atelectasis, secondary asphyxia, and pneumonia; he advises that maternity hospitals should be equipped with a suitable apparatus for treating the mother also when an anaesthetic has been found necessary. For prematurely born infants a small chamber, heated from below, may conveniently be employed for the administration of a suitable mixture of carbon dioxide with oxygen. The use of high percentages of carbon dioxide—over 10 per cent.—is unwise, except in skilled hands, but it has saved a few lives which could not have been preserved otherwise, for the deeper the asphyxial depression, the higher is the percentage of carbon dioxide required to induce breathing. The optimum amount for general use is stated to be about 7 per cent.

430 Peritoneal Bleeding from Perforation by Uterine Chorion-epithelioma

According to J. CREYSSEL and C.-E. BOYER (*Gynécol. et Obstét.*, January, 1931, p. 1) intraperitoneal haemorrhage due to chorion-epithelioma perforating the uterus is not very rare; it has a fairly characteristic syndrome, detection of which, however, may be made difficult by an exaggerated defence of the abdominal muscles. The syndrome consists in (1) signs of profuse intraperitoneal bleeding, which are of intense acuteness and gravity; (2) enlargement of the uterus to the size of a three or four months' pregnancy; and (3) a history of menstrual trouble—menorrhagia and/or metrorrhagia (especially the latter) following the last pregnancy, which may have terminated in expulsion of a hydatidiform mole. Treatment consists in panhysterectomy. Although the operative mortality in the anaemic patients who are suffering from shock is 50 per cent., and lasting cure is rare, this operation is preferable to subtotal hysterectomy, for the reason that radical cure is by no means impossible. Metastases are rarely present at the time of perforation, and permanent recovery ensues in 30 per cent. or more of operations for imperforated uterine chorion-epithelioma after radical excision.

431 Curetting in Chronic Gonorrhoea

E. J. ORSÓS (*Zentralbl. f. Gynäk.*, February 21st, 1931, p. 476) describes the case of a 2-para who had been treated in hospital for fourteen months for gonorrhoea without improvement. In spite of the presence of moderate pyrexia he curetted the corpus and cervix uteri; the convalescence was uneventful, a cervical erosion healed speedily, and gonococci were not found after the eighth day. Encouraged by this result, Orsós has performed a similar operation in 63 cases of gonorrhoea, of which two-thirds had been at least 100 days under treatment. The patients are afterwards kept in bed for eight days, and no pelvic examination is undertaken until the ninth day. Forty-five patients were speedily cured, and in three only was the operation followed by pyrexia or parametrial pain. Many writers have expressed the opinion that surgical intervention such as cervical dilatation or curetting is strongly contraindicated in cases of chronic gonorrhoea, and of the advocates of active treatment many restrict it to the cervix.

Pathology

432 Etiology of Post-operative Pulmonary Collapse

A. DEI ROSSI (*Arch. Ital. di Chir.*, February, 1931, p. 193) carried out experiments on cats and dogs which consisted in immobilizing the thorax by phrenicotomy and paravertebral neurotomy, and occluding the large and small bronchi by various methods. His experiments confirmed those of previous workers to the effect that it was possible to obtain regularly and rapidly atelectasis of parts of the lungs by complete occlusion of the corresponding bronchi. The atelectasis always developed sooner when the small bronchi were occluded than when the occlusion involved the large and moderate-sized bronchi. The introduction of thick and viscid material such as a sponge or gum into the respiratory tract never produced massive collapse of the lung, but only small scattered foci of atelectasis. Dei Rossi's experiments thus confirm the view held by American writers as to the occlusive origin of pulmonary atelectasis.

433 Dual Innervation of Striated Muscle

C. BALLANCE (*Arch. Neurol. and Psychiatry*, January, 1931, p. 1) records experiments in which the central end of the divided cervical sympathetic nerve was anastomized to the peripheral end of the divided facial nerve and to the peripheral end of the divided hypoglossal nerve. The intention was to elucidate the apparently contradictory results obtained when the central end of the cervical sympathetic nerve was united with the peripheral end of the trunk of the facial nerve. Complete functional and anatomical recoveries of the striated muscles of the face and tongue, and of the depressor muscles of the hyoid and larynx, were observed. No muscle fibres of the face or tongue muscles, or of the sterno-hyoid or sterno-thyroid muscles, appeared to be atrophied, as they should have been if a dual innervation was necessary for the complete restoration of function. The sympathetic fibres seemed to join at the anastomoses with the larger cranial nerve fibres, and there was no microscopical evidence that they continued into the cranial nerve trunks. The author is uncertain whether these experiments give any support to the view that the anatomical and functional perfection of striated muscles depends on a dual innervation, but he is inclined to think that they do. For the complete health of a striated muscle fibre, impulses must come to it from the cerebral cortex, as well as from the cells of origin of the sympathetic.

434 Dissociation of the B.C.G. Strain

R. S. BEGBIE reported last year that he had been able, by plating on Petroff's medium, to obtain three different colonial variants of the B.C.G. strain: (1) a smooth variety, with a central dome and spreading margin; (2) a rough variety, composed of heaped-up coils, and relatively compact; and (3) an intermediate variety with an umbilicated centre and a slightly crenated margin. The rough variety was similar to that described by Petroff; the smooth variety differed from Petroff's smooth type; and the intermediate variety had not been described by Petroff. In a later paper (*Edin. Med. Journ.*, March, 1931, p. 173) the author now describes virulence experiments carried out on guinea-pigs with the three variants, as well as with two different strains of the undissociated culture. Intracardiac and subcutaneous inoculations were employed, the dose in each series being equivalent to 2 mg. of the dried organisms. Many of the animals injected intracardially died, with multiple tubercles in the viscera; since the dose was large, and as no control animals injected with killed organisms were used, it is difficult to interpret the results. None of the animals injected subcutaneously died, and when killed 69 to 102 days later some of them showed, besides a local lesion, small tubercles in the internal organs. No clear-cut distinction was established between the virulence of the different variants or whole cultures examined.

The Gargle and the Child

WHILST medicine, though unpleasant to take, can be forced on the unwilling child, it is not so simple a matter to compel a child to gargle. The act of gargling cannot be enforced, and, where the actual gargle is disagreeable, few children will submit. Therefore, a very necessary act is often scamped or entirely avoided.

ODOL Mouthwash very successfully solves this problem. Its very pleasant taste appeals to the child and its proven bactericide efficiency achieves the desired results. Moreover, Odol is absolutely harmless and cannot injure the delicate mucous membrane of the child's mouth.

THE POSTAL ACCOUNT

It is often supposed that to live a long way from the nearest branch of a bank, or to be constantly unable to go to the bank in person, is a handicap to the enjoyment of the full advantages which, it is admitted, a banking account offers. Perhaps it is assumed that to conduct an account by post involves 'more letter writing', or is costly, or is not welcomed by the Bank. It is the aim of the Westminster Bank to dispel such misconceptions by a leaflet entitled *The Postal Account*, which explains the convenience of the method, and offers some clear suggestions.

The Secretary of the Bank will be pleased to send a copy on application

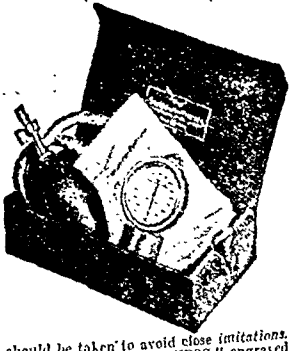
Accurate Arterial Pressure Readings

For visiting purposes the TYCOS Portable Sphygmomanometer amply fulfils the Physician's needs. Although one of the most delicate and accurate instruments of the medical man's equipment, the portable type as illustrated can be carried without fear of breakage. There is no glass tubing to break, no mercury to spill, and the readings can be verified at a glance by comparing the relation of the hand to the immovable zero.



Care should be taken to avoid close *imitations*. Look for the trade mark "TYCOS" engraved on the dial of every genuine instrument.

Obtainable from all reputable Instrument Dealers.

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS,

NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

TYKEFORD ABBEY, NEWPORT PAGNELL,

BUCKS.

FUNCTIONAL NERVOUS DISORDERS, MEDICAL & CONVALESCENT CASES.

An approved Nursing Home for reception of Female Cases under the Mental Treatment Act.

The Home is a Mansion of Historical interest, standing in 9 acres of garden and grounds, and is situated 14 miles from Northampton, and 12 miles from Bedford on the main London to Northampton Road, *fifty miles from London. Both sexes are accommodated.* Psycho-Therapeutic Treatment is used extensively in suitable cases. Radiant Heat, X-Ray, and Ultra-violet Light. Billiards, tennis, etc. Fees from five guineas per week.

Apply, Dr. D. E. M. DOUGLAS-MORRIS. *Telephone*: Newport, Pagnell 121.

THE COPPICE, NOTTINGHAM.

HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary and Temporary Patients received.

Tel.: 64117. *For terms, etc., apply to the Medical Superintendent.*

COURT HALL, KENTON, EXETER,

THE RESIDENTIAL TREATMENT OF ALCOHOLISM & DRUG ADDICTION

RENDLESHAM HALL

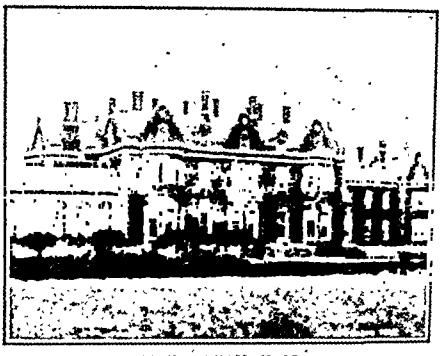
(Postal Address)—WOODBRIDGE, SUFFOLK.

Rendlesham Hall, which is open to receive patients, is essentially a Sanatorium. Its daily life and routine are that of an ordinary comfortable holiday or health resort, or of a large country house. Each patient has all the privileges of a guest consistent with the prescribed medical treatment.

Rendlesham Hall has 45 bedrooms, and about 450 acres of gardens and park. It has also a private nine-hole golf course, tennis and croquet lawns, and bowling green.

Illustrated booklet, giving particulars as to terms, etc., can be had on application to the RESIDENT MEDICAL SUPERINTENDENT.

Telegrams and Telephone: Wickham Market 16. *(Toll Call from London.)*



RENDLESHAM HALL.

Medical Superintendent: Dr. MCCLINTOCK.

BRITISH SPAS
ARE BEST

and membership of the British Spas Federation is a guarantee of efficiency

AT British Spas, treatment is only given (except in a few minor cases) upon medical prescription.

At British Spas the staffs are educated and properly trained and, in some cases, medically trained and medically certificated.

Equipment and administration are thoroughly up to date and scientific. Every new treatment is tested and reported upon before being adopted.

British Spas are also remarkably fortunate as regards situation, scenic beauty and pure air. These factors, combined with the social amenities of a home town, aid the cure considerably.

BATH Hot Springs (120° F.) Radio-active. Royal Baths extensions now open.

BRIDGE OF ALLAN Saline Water. Rich Calcium Bromide and Iodine Content.

BUXTON Radio-active Mineral Water. New Natural Baths. 3 Guineas Course.

CHELTENHAM Five Natural Waters. Modern Baths.

DROITWICH The Brine Baths Spa in charming Worcestershire.

HARROGATE 88 Waters. 100 Treatments. Medically certificated staff.

LEAMINGTON Advanced Spa Treatment. Saline Springs.

LLANDRINDOD WELLS The Modern Welsh Spa.

TREFRIW WELLS Rich Sulphate Chalybeate Waters.

WOODHALL SPA Bromo-Iodine Waters. Pinewoods. Restful Air.

¶ A New Medical Handbook is being published, specially prepared for the use of the medical profession. A copy will gladly be sent you if you will write to the Hon. Secretary, Box 1, British Spas Federation, Pump Room, Leamington Spa, or to the Managers of any of the Spas here mentioned.

HOUSE SURGEON (male) required May 15th, for a period of six months. Salary £150 per annum, with board, residence, and laundry.

Applications, stating age, qualifications, etc., together with copies of three recent testimonials, to be forwarded to the undersigned as soon as possible.

A. STANLEY BRUNT,
April 14th, 1931. Gen. Supt. & Secretary.

County Council of Middlesex.

DISTRICT MEDICAL OFFICER AND PUBLIC VACCINATOR.

The County Council invites applications from duly qualified Medical Practitioners for the undermentioned appointments:

DISTRICT MEDICAL OFFICER,
PARISH OF HAREFIELD.

Salary £45 per annum. The officer appointed will be required to carry out his duties in accordance with the Public Assistance Order, 1930, of the Minister of Health, to reside in the district, and to name to the Council some duly qualified Medical Practitioner who will, in the case of his absence or other hindrance to his personal attendance, act in his place.

PUBLIC VACCINATOR,
PARISH OF HAREFIELD.

The person appointed will be required to produce to the Council a certificate of proficiency in vaccination, unless such certificate was required as a condition of obtaining any diploma, licence, or degree which he possesses.

He will be required also to enter into a contract with the Council in accordance with the Vaccination Order, 1930, of the Minister of Health. The contract will provide for the payment of the minimum fees laid down in the Order.

Applications, stating (1) name, (2) age, (3) qualifications and experience, accompanied by copies of not more than three recent testimonials, must be received by the undersigned not later than May 9th.

No special application forms are provided. Envelopes must be endorsed "District Medical Officer" or "Public Vaccinator" as the case may be.

Canvassing, directly or indirectly, will be a disqualification.

Guildhall, Westminster, S.W.1. April 14th, 1931. ERNEST S. W. HART, Clerk of the County Council.

Nottinghamshire County Council

ASSISTANT MEDICAL OFFICER FOR MATERNITY AND CHILD WELFARE (Woman).

Applications are invited for the above appointment from duly qualified and registered women Medical Practitioners.

Candidates must have had at least three years' experience since qualification, have held a resident Hospital post, and have had considerable and recent special clinical experience in Obstetrics, Ante-natal work, and Diseases of Women.

The officer appointed will be required to devote her whole time to the duties of the office. She will be a member of the staff of the County Medical Officer, will work under his control and direction, and will be required to reside in a part of the County to be approved by him, and to carry out such duties as may be prescribed.

The salary will be at the rate of £650 per annum, rising by annual increments of £25 to £700, together with travelling allowances in accordance with the County Council's scale.

The engagement will be terminable by three months' notice on either side.

The successful candidate will be required to pass a medical examination.

Applications on the prescribed form (which may be obtained on application to me), accompanied by copies of not more than three recent testimonials, should be forwarded to the County Medical Officer, Shire Hall, Nottingham, not later than May 16th.

Shire Hall, Nottingham. April, 1931. K. TWEEDALE MEABY, Clerk of the County Council.

County Borough of West Bromwich.

HALLAM HOSPITAL.

RESIDENT HOUSE SURGEON.

Applications are invited from fully qualified male registered Practitioners (single) for the above appointment.

The appointment is for twelve months, but either party may give six weeks' notice terminating the engagement. The Hospital has 474 beds and is equipped with up-to-date special departments. There is a visiting staff of eight Consultant Physicians and Surgeons.

Preference will be given to applicants with previous Hospital experience.

Salary £250 per annum

Canvassing, either directly or indirectly, is strictly prohibited and will be deemed a disqualification.

Applications, stating age, experience, and qualifications, together with copies of three recent testimonials, must be forwarded to the Medical Officer of Health, 2, Lodge Road, West Bromwich, so as to arrive not later than by first post on Wednesday, May 6th.

Town Hall, West Bromwich. April 21st, 1931. ALFRED WICKHAM, Town Clerk.

Administrative County of London.

HOSPITAL SERVICE.

The LONDON COUNTY COUNCIL invites applications from duly qualified Medical Practitioners for appointment as TEMPORARY ASSISTANT MEDICAL OFFICERS. The persons appointed will be required to carry out such duties as may be assigned by the Medical Superintendent and, should occasion arise, to assist at any of the other establishments or medical districts under the control of the Council. The successful candidates will be required to live in the Hospitals. Male and female candidates are eligible, but lack of suitable accommodation will debar women from appointment to the Hospitals marked thus.*

The salary in each case is £250 a year, together with board, lodging, and laundry. Candidates must have held a resident appointment in a General or Maternity Hospital. The appointment will be for six months in the first instance. The duties will include the administration of Anæsthesia in Maternity cases. Vacancies exist at each of the undernamed Hospitals:

(a) * HACKNEY HOSPITAL, High Street, Homerton, E.9.
(b) MILE END HOSPITAL, Bancroft Road, Mile End, E.1.
(c) * ST. ALFEGE'S HOSPITAL, 48, Vanbrugh Hill, Greenwich, S.E.10.
(d) ST. ANDREW'S HOSPITAL, Bow, E.3
(e) * ST. JAMES' HOSPITAL, Ousley Road, Balham, S.W.12.
(f) ST. GILES' HOSPITAL, Brunswick Sq., S.E.5.

Forms of application may be obtained (stamped addressed foolscap envelope necessary) from the Medical Officer of Health (Staff Division 4a), The County Hall, Westminster Bridge, S.E.1, and must be returned by May 15th. Canvassing disqualifies. Inquiries for further details as to the nature and scope of the duties should be addressed to the Medical Superintendent at the Hospital.

Candidates need not complete a separate form in respect of each Hospital, but may indicate on their application forms a preference for a particular Hospital.

MONTAGU H. COX,
Clerk of the London County Council.

Administrative County of London.

HOSPITAL SERVICE.

The LONDON COUNTY COUNCIL invites applications for appointment as male ASSISTANT MEDICAL OFFICER at the Hospital and Institution below. The person appointed will be required to carry out such duties as may be assigned by the Medical Superintendent and, should occasion arise, to assist at any of the other establishments or medical districts under the control of the London County Council. The successful candidates will be required to live in the Hospital or Institution.

Candidates must be qualified Medical Practitioners of at least one year's standing, and have held a resident appointment in a General Hospital for at least six months.

I. ST. MARY ABBOTTS HOSPITAL, Marloes Road, Kensington, W.8. Salary £350 a year, rising by annual increments of £25 to £425 a year, together with board, lodging, and laundry. There is no accommodation for a married man.

II. CONSTANCE ROAD INSTITUTION, East Dulwich, S.E.22, under the control of the Medical Superintendent of Dulwich Hospital. Salary £250 a year, together with board, lodging, and washing. The duties are mainly Medical. The appointment will be for one year only.

Forms of application may be obtained (stamped addressed foolscap envelope necessary) from the Medical Officer of Health (Staff Division 4a), The County Hall, Westminster Bridge, S.E.1, and must be returned by May 15th. Canvassing disqualifies. Inquiries for further details as to the nature and scope of the duties should be addressed to the appropriate Medical Superintendent.

MONTAGU H. COX,
Clerk of the London County Council.

The Radium Institute,

Riding House Street, London, W.1.

Applications are invited for the post of HOUSE SURGEON. Candidates must be fully qualified and unmarried. The appointment is for a term of six months, and the successful candidate will be required to take up his duties at an early date. The salary will be at the rate of £150 per annum, with board, lodging, and laundry.

Applications, stating age, qualifications, and experience, with copies of three recent testimonials, must be received at the Institute as early as possible.

Canvassing, either directly or indirectly, is not permitted.

THOS. A. GARNER, Secretary.

City of Birmingham.

DUDLEY ROAD HOSPITAL.

JUNIOR ASSISTANT MEDICAL OFFICERS (Male).

Applications are invited from fully qualified Medical Practitioners for appointments as Junior Assistant Medical Officers (male) at the Dudley Road Hospital.

The Hospital has [illegible] beds, divided in Infectious, M. Obstetric Sections. There are completely equipped Pathological and Biochemical Laboratories, Deep Therapy, X-Ray, Electrical Massage, Sunlight and Dental Departments. Approximately 5,000 operations are performed annually.

The appointments will be for a period of six months in the first instance, but may be extended at the end of that time for a further period not exceeding six months.

The persons appointed will be required to assist at operations, to administer anæsthetics, and undertake casualty work and such other duties as may be assigned to them by the Medical Superintendent.

The salaries attached to the appointments will be at the rate of £200 per annum, together with full residential emoluments (rations, apartments, laundry, and attendance).

The officers appointed will be required to pay to the Council all fees, allowances, and emoluments (other than the foregoing) received by them.

Further particulars of the appointments may be obtained from the Medical Superintendent, F. W. ELLIS, Esq., M.D., F.R.C.S., Dudley Road Hospital, Birmingham, to whom applications, stating age, experience, and qualifications, accompanied by copies of recent testimonials, should be forwarded not later than Thursday, May 7th.

F. J. SYMONS, Secretary.
April 28th, 1931.

The Royal Aberdeen Hospital for SICK CHILDREN.

A CLINICAL ASSISTANT is required in the Department of Anæsthetics. Honorarium £50. The post will be tenable for one year. Applications from qualified men to be addressed to Mr. A. S. R. Bates, Hon. Secretary, 12, Dee Street, Aberdeen.

City and County of Kingston-upon-Hull.

HULL MUNICIPAL MATERNITY HOME AND INFANTS' HOSPITAL.

JUNIOR RESIDENT MEDICAL OFFICER (Woman).

The Corporation invite applications from unmarried or widowed Women Medical Practitioners for the appointment of Junior Resident Medical Officer at the Maternity Home and Infants' Hospital, Hedon Road, Hull.

Salary is at the rate of £100 per annum, together with board, washing, and residence at the Maternity Home.

The appointment is limited to a period of one year.

The Medical Officer appointed will be given every opportunity of obtaining post-graduate experience in abnormal cases of midwifery, in the treatment of dietetic errors in children, and in the treatment of venereal diseases in pregnant women.

She will be required to devote the whole of her time to the duties of the appointment, which will also include opportunities for occasional attendance, for the sake of experience, at Ante-natal, Post-natal, and other clinics. She will also act as Anaesthetist at the Maternity Home.

Conditions of appointment and forms of application may be obtained from the undersigned

Completed applications (in an envelope endorsed "Junior Resident Medical Officer, Maternity Home"), together with copies of three recent testimonials, must be received not later than mid-day on Wednesday, May 13th.

Health Department, Guildhall, Hull. W. M. FRAZER, Medical Officer of Health.

Borough of Ilford.

APPOINTMENT OF ASSISTANT MEDICAL OFFICER OF HEALTH.

The Corporation invites applications from legally qualified Medical persons of both sexes for the office of Assistant Medical Officer of Health, for duties in connection with Maternity and Child Welfare work, School Medical Inspection, and General Public Health work. Candidates for the appointment must have had special experience in Midwifery and Ante-natal work since qualification, and subject to this, preference will be given to candidates who possess the Diploma of Public Health or similar qualification, and have had definite experience in Children's Diseases.

The commencing salary of the officer will be £600 per annum (no bonus), rising by one annual increment of £50, and two annual increments of £25, to £700 per annum.

The person appointed will be required to devote whole time to the duties of the office, to reside within easy distance of the Corporation's Maternity Home, and to enter into an agreement for the due performance and fulfilment of all the duties and conditions governing the appointment. The appointment will be subject to a satisfactory medical examination, and to the provisions of the Local Government and Other Officers Superannuation Act, 1922.

Applications, which must be made on forms obtainable (with list of duties) from the undersigned, accompanied by copies of three recent testimonials (which will not be returned), endorsed "Assistant Medical Officer of Health," must be received at my office, at the Town Hall, Ilford, not later than Thursday, May 14th.

Canvassing members of the Council, directly or indirectly, is prohibited and will disqualify.

By Order,
ADAM PARTINGTON,
Town Clerk.
Town Hall, Ilford.
April 20th, 1931.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)
(FOUNDED 1880.)

12, Stratford Place,

Tele. Address: Triform, Wesdo—London. **Oxford Street, W.1.** Telephone: Mayfair {1782 / 1783}

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION have every confidence in recommending its members to consult Mr. A. V. STOREY, the General Mana , in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of fully qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.

10-13, BEDFORD STREET, STRAND, LONDON, W.C.2.

Telegrams: BOVMEDICAL, WESTRAND-LONDON. Telephone: TEMPLE BAR 1616 (3 Lines).

Under the personal directorship of Dr. J. FIELD HALL and J. C. NEEDES
who have both had many years' experience as Medical Transfer Agents.

The commission chargeable in respect of any practice or partnership in Great Britain placed exclusively in the hands of this Agency has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being fifty pounds (£50).

No charge is made to Principals for the introduction of Locum Tenens or Assistants.
Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.

1. SURREY.—COUNTRY PRACTICE.—Very old-established, and situated in delightful district. Gross cash receipts for past 12 months £2,060, including panel of about 700. Fees from 2/6 to 21/-. Midwifery 3 to 20 gns. Exceptionally nice house, with 2 reception, 6 bedrooms, and professional rooms. Nearly 2 acres of garden. Price, freehold, £3,000, £1,800 on mortgage. Premium £3,000.

2. CHESHIRE.—NEAR COAST.—Old-established good mixed-class PRACTICE, averaging for the past 3 years nearly £1,600, including panel of 1,283. Very good house in 3 acres of ground, with 2 reception, 4 bedrooms, etc. Rent on lease £85 p.a. Premium £2,300.

3. PARTNERSHIP.—HOME COUNTY.—Within 40 miles.—In a small country town, in very pleasant district, the third share, with increase later, of an old-established mixed-class Practice offering good scope. Cash receipts average over £3,000 p.a., including panel nearly 1,700 and appts. Good house, with 3/4 of an acre of garden, tennis court, etc. Rent on lease £65 p.a. Premium 2 years' purchase. Ingoing partner should be about 30, English or Scotch, and pref. married.

4. WITHIN 30 MILES OF LONDON.—In a delightful residential district (well populated and growing rapidly), a small PRACTICE, producing last year £400, including panel of 300, and capable of considerable development. Very good residence (suitable for resident patients) in about 2 acres of ground. Price, freehold, £4,000. Mortgage arranged. Premium £400. Excellent schools, good society, and sport.

5. FAVOURITE COAST TOWN.—Old-established good middle and better-class PRACTICE, producing over £1,800 p.a. Selected panel of under 400. Fees 5/- to 10/6. Very little midwifery. Commodious house, with 2 reception, 6 bedrooms, etc. Large garden. Freehold for sale. Premium £3,000.

6. SOUTH OF ENGLAND.—Pleasant Town near sea coast.—Very old-established PRACTICE (partly Surgical), averaging over £2,400 p.a. (last year £2,516), including panel of 500. Centrally situated house. Price for Practice and house £5,000. Successor should also have some knowledge of Eye, Ear, Nose, and Throat work.

7. DEATH VACANCY.—LANCS.—LARGE TOWN.—Old-established PRACTICE, averaging about £500 p.a., but capable of much increase as district is growing. Panel of 250. Fees 3/6 to 10/6. Suitable accommodation can be secured. Premium £500 or near offer.

8. HOME COUNTIES.—Within 40 minutes' run of London.—Old-established mixed-class and increasing PRACTICE, situated in small town with pleasant surroundings. Cash receipts average £1,725 p.a., including appt. £70 and panel 1,000. House with good accommodation and small garden. Price for freehold £2,500. Premium 1½ years' purchase. Educational facilities.

9. PARTNERSHIP.—SOUTH-WEST LONDON.—A one-third share is for disposal in very well-established chiefly middle-class Practice, producing last year about £5,500, including panel (rapidly increasing) of 1,500. Fees from 2/6. Suitable house can be rented on lease. Premium 2 years' purchase.

10. PARTNERSHIP.—MIDLANDS.—Prosperous Town within 80 miles of London.—A one-third or five-twelfths share is for disposal owing to the retirement of the second of three partners in an exceptionally sound mixed-class Practice. Average gross cash receipts £3,300 p.a., including panel of 1,000. Fees 2/6 to 25/-, medicine extra. Premium only 1½ years' purchase for quick sale, owing ill health.

11. ESSEX.—PARTNERSHIP.—Practice is situated in developing neighbourhood, within easy reach of town. A one-half share is offered in steadily increasing Practice bringing in nearly £2,700 p.a., including panel of 1,000. Very nice house, with three reception, six bedrooms, etc., and good garden. Price £1,400, part on mortgage. Premium 2 years' purchase. Good scope for Surgery.

12. LONDON, WEST. and increasingly mixed-class PRACTICE, past 12 months £1,790, including panel of No midwifery. House in excellent repair, contains 2 reception, 4 bedrooms, bathroom, etc. Price for freehold £2,500. Premium 2 years' purchase.

13. LONDON, E.C. (nr. Holborn Circus).—Old-established mainly working-class PRACTICE, averaging over £700 p.a. (last year £750), including recently started panel of 360. Fees from 2/-. No midwifery. Six-roomed house, with good professional accommodation. Rent on lease £95 p.a. Premium £1,000.

14. LONDON, EAST.—Well-established mixed-class PRACTICE, averaging about £1,150 p.a., including panel of 1,400. Small house, with 1 reception, 2 bedrooms, etc., and 3 professional rooms. Rent on lease £13 per quarter. Premium £2,000.

15. SOUTH AFRICA.—Within 8 hours of Durban.—Rapidly increasing PRACTICE in very pretty township near sea coast, producing last financial year over £1,700, including appt. £120. Practically all fees, which are good, are paid in cash. Opposition negligible. Bungalow residence in about one acre of ground. Rent £84 on lease. Premium £1,500, to include furniture, drugs, instruments, and motor car (£1,525 without latter), payable £1,000 down and balance by easy instalments. Excellent climate and sport.

16. NORTH WALES.—PARTNERSHIP.—A one-third share is offered in a good mixed-class Practice producing over £1,700 p.a., including panel of 470 and appts. of about £100 p.a. Fees 3/6 to 21/-. Purchaser, if bachelor, could reside with Vendor. Good sport and schools. Premium 2 years' purchase.

17. SURREY.—Increasing residential district, with good train service to town.—Well-established good general PRACTICE, offering Surgical scope. Gross cash receipts for last 12 months nearly £5,200, with panel of about 900. Visits 5/- to 21/-. Suitable house, with 3 reception, 7 bedrooms, etc. Can be bought or rented on lease. Premium 1½ years' purchase.

18. SOUTH CORNWALL.—Near Sea.—Well-established PRACTICE producing about £700 p.a., including panel of over 600. Fees 5/- to 21/-. Suitable house, with 3 reception, 5 bedrooms, etc. Rent on lease £50 p.a. Good sport and mild climate. Premium 1½ years' purchase. Ill-health reason of sale.

19. WEST MIDLANDS.—Easily worked PRACTICE in residential village within easy reach of two good towns, and having very pretty surrounding country. Receipts average over £1,000 p.a., including panel of 500 and an appt. worth £150. Nice house with good garden and land of about 2 acres. Price for freehold £1,600. Fishing, hunting, etc. Premium 1½ years' purchase.

20. SOUTH WEST OF ENGLAND.—Near the Sea.—Old-established unopposed and easily worked Country PRACTICE, in beautiful district, within easy reach of Market Town. Receipts just under £1,100 p.a., including appts. and panel £550. Exceptionally attractive house in three acres of ground, with ample accommodation. Water laid on and electric light available shortly. Price freehold £2,600, part on mortgage. Premium £1,600. Sport and schools within reach.

21. YORKS.—LARGE TOWN.—Old-established chiefly good working-class PRACTICE averaging about £1,300 p.a., including panel of 1,400. Fees from 2/6. Suitable house, with 3 reception, 4 bedrooms, and dressing room, etc. Garden; garage. Price £1,200. Premium 1½ years' purchase, chiefly by instalments.

22. LONDON, SOUTH-EAST.—Woman Doctor's PRACTICE, producing £560 immediate past 12 months. Panel of 152. Fees 2/6 to 21/-. Suitable flat can be rented at £60 p.a. Premium £650, or near offer. Very good scope for increase.

23. LONDON, WEST.—Small good class PRACTICE, at present bringing in about £450 p.a., but offering large scope. Panel of 300. Fees 5/- to 21/-. Good house for sale. Premium £500.

24. YORKS. — HOSPITAL TOWN. — Old-established sound middle and working class PRACTICE, producing about £1,300 p.a., including panel of 1,300, and appts. worth £50. Fees from 5/6. Small house with one reception, 3 bedrooms, bowroom, etc. Premium 1 to 1½ yrs.' purchase, payable by arrangement. Ill health reason for sale.

25. NORTH LINCS.—COAST TOWN.—Old-established PRACTICE, producing last year nearly £2,900 p.a., including panel of 1,700. Fees 3/6 to 21/-. Practically unopposed. Good modern house, with special professional rooms. Nice garden. Garage. Freehold for sale, part on mortgage. Good sport and schools within reach. Premium 1¼ years' purchase.

26. NORTH OF ENGLAND.—GOOD TOWN.—A one-third share is offered in a very sound PRACTICE averaging about £5,000 p.a. Ingoing partner must be well qualified, not over 35, and interested in medicine. Suitable house available. Premium 2 years' purchase.

27. NEAR HEREFORDSHIRE BORDER.—A one-third to one-half share in a well-established good class non-dispensing PRACTICE, producing about £1,800 p.a. Panel of over 500. Good house can be rented at £60 p.a. Sport of all kinds. Premium 1½ years' purchase, part by instalments. Welsh not necessary.

28. CHESHIRE.—COAST TOWN, within reach of Liverpool.—Well-established PRACTICE, averaging over £1,200 p.a., including panel of 780. Fees from 3/6. Mid. 2 to 5 gns. Double-fronted house, with 3 reception, 4 bedrooms, etc. Price for freehold £1,200, £800 on mortgage. Premium £1,100 for quick sale.

29. CORNWALL.—VILLAGE PRACTICE, within easy reach of Plymouth.—PARTNERSHIP.—A one-half share in a very old-established mixed-class Practice, averaging £2,563 p.a., including panel of 850. Fees 3/6 to 21/-. Not much midwifery. Good house, with 3 reception, 6 bedrooms, etc. Large garden. Price for freehold £2,000. Sport of all kinds. Premium 1½ years' purchase.

30. SOUTH-WESTERN COUNTY. — Hospital Town. — Good mixed class PRACTICE, averaging £859 p.a., including small panel of 140, and appt. worth £40 p.a. Visits 5/- to 10/6. Not much midwifery. House, with 3 reception, 4 bedrooms, etc. Garden. Garage. Price for freehold £1,600, half on mortgage. Very good schools and sport. Premium £1,300.

Full Schedule of Terms and Conditions will be forwarded on application.

SAVED BABY'S LIFE!

PORTE'S CAESAREAN OPERATION

In 'The Scottish Nurse' for January 1931 appeared an article by a Scottish State Registered Nurse describing an exceedingly severe operation—*Porte's Caesarean Section*—which she underwent in Malta at the hands of a well-known surgeon.

Twenty-four hours after the second stage of labour had begun it was discovered that delivery was impossible. The womb had become septic and the Porte Caesarean was performed, the baby being safely extracted.

The condition of the mother was then highly critical, and the baby had to be revived by artificial respiration. For a week after birth she weighed only five pounds. The mother, despite intense pain and weakness, endeavoured to nurse her, but as progress appeared stationary she was put on alternate feeds of Cow & Gate Full Cream Milk Food and Breast.

From then onwards she made rapid progress and at four months the mother weaned her altogether.

Now eight months old, the child is the picture of contentment and happiness and weighs over 17 pounds.

COW & GATE MILK FOOD

has saved more baby lives than any other preparation in the world

The best milk for babies, when natural feeding fails.

FATIGUE

is not a

DISEASE

An exhausted man is not a sick man and general low vitality can not be classified as a pathologic condition.

Patients with low vitality and lack of strength, however, need some treatment to restore their physical and mental depression just as much as a tired athlete needs rest.

The "tonic effect" to the organism and the increased energy-liberating metabolism may be accomplished by the administration of

The "Allenburys"

"CHARKAOLIN"

GRANULES

"Charkaolin" is a highly efficient agent for the treatment of intestinal infections characterized by abnormal fermentation and the formation of toxins. It combines the absorbent properties of highly activated vegetable charcoal with the well-known toxin adsorbing qualities of "Osmo" Kaolin.

It is in the form of fine, clean granules which disintegrate rapidly in water and diffuse their ingredients evenly throughout the liquid. "Charkaolin" is tasteless, forms a fine suspension in water and is, therefore, quite easy to take.

Descriptive literature and a clinical trial sample will be sent on application.

The Therapeutic value of BRANDY—

its lifting and sustaining powers—as compared with other spirits depends on the presence or absence of the higher Alcohols or Ethers. These in turn depend on Grape, Soil, Stills employed, Climate, Storage, Selection and Experience.

It is quite easy to make a spirit from grape wine—It is neither easy nor cheap to make a Brandy containing the qualities you want.

Cognac Brandy alone provides them.

Take no risks; ensure the results you expect

Prescribe Brandy distilled in Pot-Stills from Wines grown in the best Cognac districts; Matured in warehouses which have been filled with Cognac Brandy for centuries; Made by Men with the inherited Experience of Seven Generations.

In short—Prescribe MARTELL'S BRANDY

and know that you are doing the best possible for your patients.

BANTAM Coffee

Bantam Coffee is prepared from the finest selected Empire grown beans which are powdered and all the waste grounds extracted so that it dissolves instantly and completely when hot water or milk is added. A little Bantam Coffee dropped in a glass of warm milk makes a very palatable beverage. Bantam Coffee is absolutely free from adulterants and has been awarded the certificate of the Institute of Hygiene.
A 2/- tin yields 50 cups of delicious coffee.
Dept. 68. BANTAM PRODUCTS LTD., LEEDS.
Samples for testing will be sent on application.

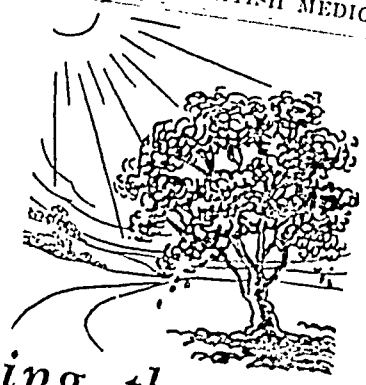
Ladies' Department on First Floor.



Well, here's May... are you going through another Summer without your Frigidaire?

Remember how you wished you had one, that hot spell last August? And then came a rush of work and you forgot about it . . . there's a coupon on this page to prevent that happening again. You'll want your Frigidaire badly during the coming hot weather, apart from health reasons.

There's the cool clink of ice in a glass when you're hot and tired—cold, sweet draughts of milk for the children—and all your food tasting better and more appetising because it is kept really fresh. Don't delay any longer—send the coupon to-day.

Frigidaire incorporates all the conveniences and refinements that you would wish to have in your electric Refrigerator. Here are just a few of them.

The Quickube Ice Tray, enables single cubes, or many, or all, to be extracted at once, simply by a light pressure of the finger. No melting them out under the tap. Your cocktail ice is ready at a moment's notice. This is an exclusive Frigidaire feature.

The Cold Control, by which the freezing of ice cubes or any other frozen delicacy can be accelerated at will.

The automatic feature of Frigidaire is invaluable. The safety of your food does not depend on a maid's vigilance. Frigidaire maintains a dry cold that is always under 50° —the only safe temperature for food.

Practical, flat top makes a useful shelf.

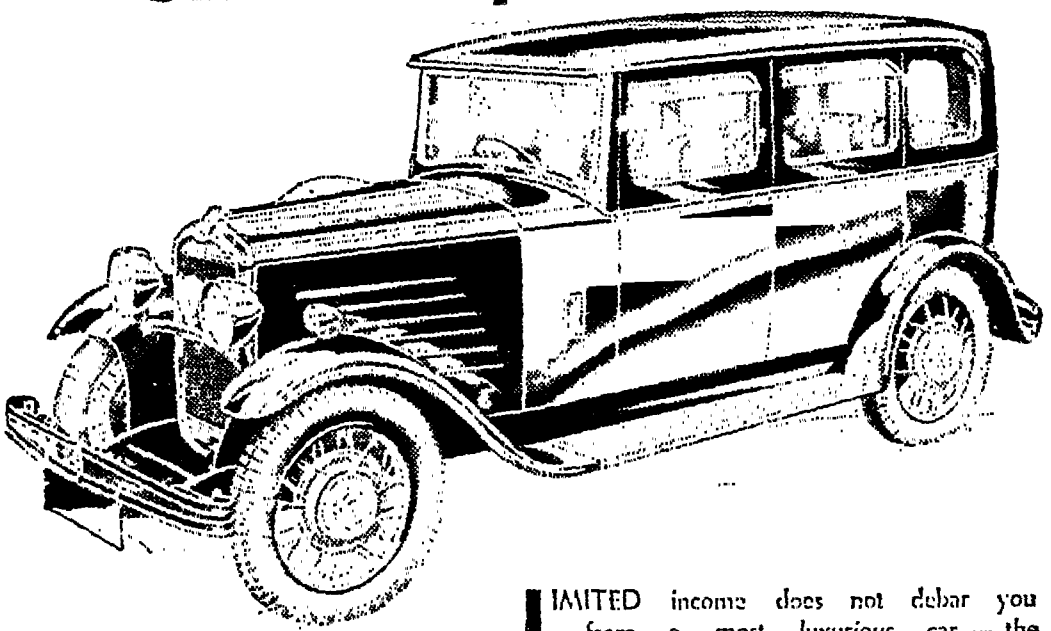
Own a Luxury Car this time



LIMITED income does not debar you from a most luxurious car — the Singer "Six."

Deep, leather upholstered seats, ample leg, elbow and head room, FOUR SPEED GEAR BOX—vacuum SERVO BRAKES, SAFETY TANK at rear (outside the coachwork) centralised finger tip controls, thermo controlled radiator—these are a few of the luxury car features which are yours at £280.

You can loll back in drawing room comfort, and hum down the roads at a silent "60" if you wish —yet you cannot find a car more docile in traffic, or easier to drive.

Don't condemn yourself to an ordinary car. See this Singer "Six" and be enraptured.

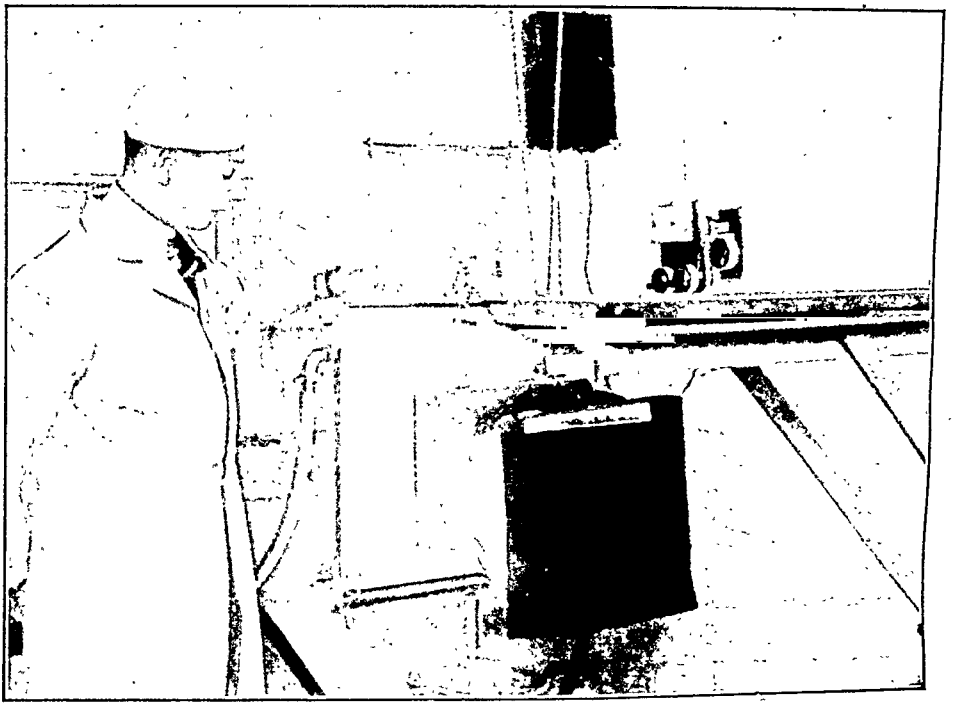
MICKLEFIELD IRRADIATED MILK



TREATING THE MILK

By this Process—

(1) VITAMIN A AND NATURAL FLAVOUR ARE PRESERVED.
(2) VITAMIN D CONTENT IS INCREASED 1,800 PER CENT., OR TEN TIMES THAT OF ANY OTHER IRRADIATED MILK.

One pint equivalent in Vitamin D to 600 drops or 12 grammes of average Cod-Liver Oil.

A further ten weeks' test recently conducted at the Infants' School, Rickmansworth, under the supervision of the Medical Officer of Health, gave the following increases in growth:—

(1) 18 children (controls) had their usual ordinary milk.
(2) 29 " 1/3-pint of Grade A (T.T.) milk five days a week.
(3) 30 " " Micklefield " " "

(1) Averaged .547-in. | (2) Averaged .526-in.
(3) Averaged .777-in., or nearly 50% more than the other two.

These tests have now come to an end because all the children wanted Micklefield Irradiated Milk.

Full particulars appeared in an article in the LANCET, January 18, 1930, p. 127, et seq., a reprint of which will be sent post free on request.

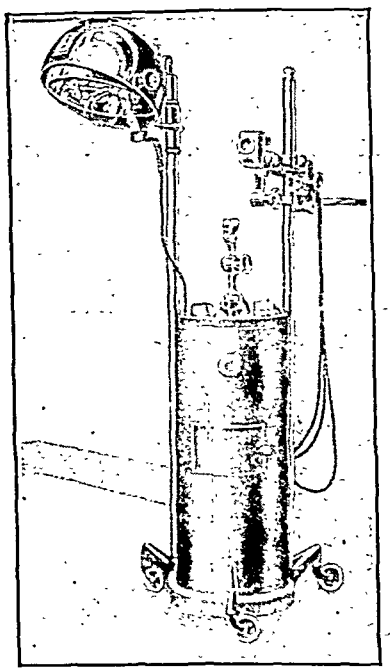
The milk is delivered every week-day in London; elsewhere by arrangement.

Write to J. O. HICKMAN, MICKLEFIELD GREEN, RICKMANSWORTH.

ACTINOTHERAPY

Two Famous Lamps in Combination —

for general, orificial or localised conditions



THE COMBINATION UNIT
Alpine Sun Lamp and Kromayer Lamp

THE combination unit illustrated here provides two ultra-violet lamps in one.

It is specially designed to meet every requirement of the practitioner or specialist in administering actinotherapy. It provides, in one outfit, for general, local or orificial treatment. This new Hanovia unit is the most up-to-date model of its kind in existence to-day. Mobile and self-contained, it has outstanding advantages for use in clinic or hospital.

Hanovia specialise in actinotherapy equipment and in nothing else—they are both leaders and pioneers in this field.

Return the coupon below for details of this unit and other Hanovia models, a full list of free reprints, or any other information you may require. Mark your enquiry Dept. 9.

Latest Prospectus sent FREE on request.

Feen-a-mint

REG. TRADE MARK

The Chewing Laxative

Peristaltic Promotion

Feen-a-mint definitely promotes peristalsis without griping, and without irritation to the intestinal or reno-vesical mucosa. Its marked activity is due to the minute state of sub-division of its active principle (phenolphthalein) which is incorporated into a resinous gum base. Mastication assists further its division—thus a maximum therapeutic effect is exhibited.

Definite Defaecation

Feen-a-mint is valuable at all ages. It is a beneficial aid in 'difficult' and intractable cases—especially those due to habit-forming drugs, pregnancy, neglect and post-operative stasis. It has no secondary effects, and is not incompatible with any concurrent treatment. Pleasant to take, bland, yet certain in result, and non-habit-forming, Feen-a-mint is free from all objection to the patient.

Feen-a-mint is of marked assistance in

Then and Now

1903

"It is unlikely that starch will form a suitable food for young infants."*

1930

"Young infants even as early as the third month will digest appreciable quantities of starch perfectly."†

The paramount importance of starch in infant feeding at a very early stage is generally admitted to-day. Leading practitioners are occupied with the question of the best and most digestible form in which it can be administered.

There is a consensus of opinion in favour of wheat as opposed to oats as a first solid diet, both because its carbohydrate is known to be better tolerated and less rachitogenic than that of oats, and because it has greater digestibility and energy value.

During 1930, a leading biochemical society proved by careful experiment that "Cream of Wheat" was superior to oatmeal. After 4 hours the digestion of oatmeal was almost at a standstill, while that of "Cream of Wheat" continued at a scarcely diminished level *for another 4 hours*. When digestion was complete, the sugar yield from "Cream of Wheat" was 50% greater, and productive therefore of 1½ times as much energy.

As a first solid diet, as a food for children suffering from indigestion or intolerance of fat, and as a post-operative diet for adults, "Cream of Wheat" can be confidently given.

On receipt of your professional card, *Dept.* W.4, Fassett & Johnson, Ltd., 86, Clerkenwell Road, London, E.C.1, will be glad to send you a sample of "Cream of Wheat" and fuller details of the above-mentioned tests.

* Written statement by a leading authority on Infant Feeding.
† "*Infant Feeding*," by Clifford G. Grulee, A.M., M.D., LL.D. (J. & A. Churchill)

MAKE COW'S MILK DIGESTIBLE

The chief drawback to cow's milk in infant feeding is that it forms a clot on reaching the stomach—hence indigestion. It is the special function of Robinson's "Patent" Barley to prevent the formation of this indigestible clot, and the accompanying photographs taken in our own Research Laboratory prove that this can be done. They are "in vitro" reproductions of the "in vivo" conditions prevailing in the infant's stomach.

RADIOSTOL

(Irradiated Ergosterol)

That Vitamin D in ample quantities is an essential part of the diet of early childhood is now generally recognised, the architecture of the teeth and the correct development of the skeletal frame being dependent upon the ingestion of a sufficiency of this vitamin.

In the early months of life

This sufficiency is assured when Radiostol—*the original British irradiated ergosterol*—is administered:—

(1) to the mother during pregnancy and lactation
(2) to the child as soon as it is fed independently of the mother.

Radiostol therapy ensures the ingestion of Vitamin D in accurately-standardised amounts. Radiostol, being non-toxic, possesses the further advantage of producing no ill-effects even when administered in doses greatly exceeding the normal daily requirement of Vitamin D.

TWO NEW PREPARATIONS

Vide THE LANCET, Jan. 10th, 1931.

"PSYLLA (psyllium seed); LACTO-DEXTRIN (Battle Creek Food Company, Mich., U.S.A., Distributing Agents, Coates & Cooper, 41, Great Tower Street, London).—This company have sent us specimens of their laxative agent, Psylla, and their preparation, Lacto-Dextrin, for use in intestinal toxaemia. Psyllium seeds when immersed in water yield a mucilaginous substance which is able to take up relatively large quantities of water to form a gelatinous mass. They become in this way a useful lubricant, while the emollient character of the mass renders it of special service in Fissure or Haemorrhoids. The same firm has received favourable reports from the clinical use of their combination of lactose and dextrin."—*Lancet*, Jan. 10th, 1931.

Samples and literature of both these intestinal products will be sent to members of the Medical Profession on request to Coates & Cooper, 41, Great Tower Street, London, E.C.3, Sole Distributing Agents for the United Kingdom and Irish Free State.

IDOZAN HAS BEEN REGULARLY PRESCRIBED BY DOCTORS IN FIFTEEN DIFFERENT COUNTRIES

As a restorative in convalescence and in cases of anaemia

Colloidal Iron Concentrate	83%
Pure Alcohol	6%
Sugar	10%
Flavouring	1%

That is the formula of this tonic preparation, which contains a larger percentage of assimilable iron than has hitherto been provided in either a general or colloidal form. A more rapid response may therefore be anticipated from the administration of this preparation, which is very pleasant to take and well tolerated by all patients. Idozan has no constipating effect, it does not derange the stomach or discolour the teeth. Though incompatible with alkaline salts, it may be combined with Liq. Arsenicalis and vegetable tinctures. It is therefore very suitable for therapeutic administration, where it is desired to give large doses of iron; both as a restorative after illness and in cases of anæmia it can be prescribed either with or without additional drugs with confidence and freedom.

FEEDING IN CACHECTIC DISEASES

Owing to its chemical combination of casein and sodium glycerophosphates Sanatogen is of the utmost value in cachectic diseases. Sanatogen introduces casein into the organism, in a form in which it can be assimilated even by patients with greatly decreased powers of absorption. At the same time the glycerophosphates regenerate and strengthen the whole system.

IN TUBERCULOSIS:

Sanatogen increases the weight, has a strengthening influence on the nerves, enriches the blood and overcomes the "run-down" feeling of the patients ["British Journal of Tuberculosis."]

IN SYPHILITIC CACHEXIA:

Sanatogen overcomes the nerve-weakening influence of the specific treatment [Col. Lambkin in "The Lancet," Vol. CLXXI, No. 4340.]

Samples and literature on request to
Genatosan Ltd.

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl-salicylic acid possesses a notable disadvantage. Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach. Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced.

"Alasil" completely overcomes this objection. By combining calcium acetyl-salicylate with "Alocol," unfavourable secondary action upon the stomach is prevented. This beneficial influence is undoubtedly due to the presence of "Alocol" (Colloidal Hydroxide of Aluminium), which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract. "Alasil" is therefore a triumph over acetyl-salicylic acid. It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time. Analgesic, Antipyretic, and Sedative. "Alasil" is indicated in all cases where acetyl-salicylic acid has been used heretofore.

A supply for clinical trial with full descriptive literature sent free on request.

PREVENTION OF CANCER

ONE of the most noted authorities on Alimentary Toxæmia is firmly convinced of the importance of this condition in the production of Cancer.

The irritant effects of the stagnating contents of the bowel on the intestinal mucous membrane, accompanied as it often is with ulceration, is obviously a cause of Cancer in the bowel itself. According to this writer, the toxins absorbed produce atrophic changes in the breast and other organs which are specially prone to be followed by Cancer.

There are grounds, therefore, for hoping that the use of the most efficient of all intestinal disinfectants—Kerol—for prevention and cure of alimentary toxæmia, will do much to prevent the occurrence of Cancer.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

The confidence of the MEDICAL PROFESSION.

Benger's Food has gained its unique position not by extravagant or sensational claims but by the constant recommendation of Medical Practitioners.

Benger's Food is scientifically prepared to adjust fresh cows' milk, diluted or undiluted, to suit the individual requirement of the patient. In this respect it is distinct from any other food obtainable.

Benger's Food is largely used as a routine treatment in all cases of impaired digestion. The following comments, recently made by Doctors, indicate some specific conditions in which the Medical Profession prescribes Benger's Food.

DYSPEPSIA.

"routine food in all cases of dyspepsia and disordered digestion."

"used for invalids and all gastric cases."

INFLUENZA.

"very largely used for Influenza in all its forms."

CANCER.

"invaluable for cancer of the throat."

"cancer of the stomach—doing well on Benger's Food."

THE AGED.

"very beneficial for man of greatly advanced years."

"invariably used for invalids and aged persons."

when you forbid a patient caffein please hasten to add—

When a patient's face falls at your order to avoid caffein, please hasten to add a word of cheer.

Console the patient with the fact that, in forbidding caffein, you are not forbidding the satisfying flavour of coffee. Remind the patient that he can still drink H.A.G. Coffee—genuine, delicious coffee with the effects of caffein minimized.

There is, however, another reason besides your own benevolence for recommending H.A.G. Coffee. By letting your patient enjoy the rich and satisfying flavour of H.A.G. Coffee, you remove all temptation to drink caffein-containing coffee on the sly.

Rich in flavour—tempting in aroma

H.A.G. Coffee is real coffee—a superior blend of the choicest Central and South American coffees. The decaffeination process takes place *before* the coffee beans are roasted. This leaves intact all the mellow flavour and fragrance that make coffee "the beloved beverage." Coffee experts recognise that no other blend is finer.

H.A.G. Coffee is under the Independent Control of The Institute of Hygiene and British Analytical Control.

Your grocer stocks H.A.G. Coffee—ground or in the bean and in vacuum tins that preserve its freshness and its fragrance. Or send the coupon below for a liberal sample tin of H.A.G. Coffee. With it we shall be pleased to send a copy of "Some Observations of the Action of Caffein," a more complete discussion of H.A.G. Coffee. Send the coupon now.

THE TUBERCULOSIS DANGER!

It has been stated in Parliament that *over two thousand children die every year through tuberculous milk.* How many children who survive grow up weaklings through the taint of bovine tuberculosis? This hardly bears thinking about. Cow & Gate Milk Food is guaranteed absolutely free from tuberculosis and other pathogenic organisms.

Read the following extract from the Presidential Address at the Royal Sanitary Institute Congress at Margate, it is of vital significance to the medical and nursing professions:

'The loss on the agricultural and veterinary side of 52,222 bovines during the three years 1926, 1927, 1928, slaughtered under the Tuberculosis Order of 1925, and at least twice that number not reported but otherwise disposed of, the estimate that 40 per cent. of the cows of our dairy herds producing milk for human consumption are tuberculous, are circumstances in themselves that demand immediate attention. But when to this is added the fact that in England 31.5 per cent. of tuberculosis in children up to 15 years is of bovine origin, and deaths from tuberculosis in children up to 5 years is 29.5 per cent. of bovine origin, that 57 per cent. of cervical adenitis in the same ages is of bovine origin, that 33 per cent. of bone and joint tuberculosis in children under 5 years and 24 per cent. in children from 5 to 10 years is of bovine origin, that in Scotland it is recorded that in certain hospitals in Edinburgh as much as 90.3 per cent. of cervical adenitis and 61.2 per cent. of bone and joint tuberculosis in children up to 12 years is of bovine origin, it is high time that this grave condition and this very serious menace to public health should be mended and ended. It is no credit to us as scientists and protectors of public health that such a state of affairs should be permitted to continue, or even to exist.'

-IS SAFE!

Another remark made at the meeting was as follows:

'It would be better to have no milk supplied at all than to feed children on diseased milk as is being done at present.'

Cow & Gate Milk Food

"The best milk for babies, when natural feeding fails."

COW & GATE MILK FOOD

is prepared by our Special Improved Roller Process employing a short heat treatment which destroys all disease organisms but leaves the natural vitamins unimpaired. It is a basic milk food which can be modified by the profession as they desire to suit each and every case.

EVANS'
COLLOIDAL SPECIALTIES

Being suitably protected, Evans' Colloidal preparations are stable to an unusual degree. Their effectiveness is therefore not impaired by factors which often destroy the Colloidal state.

COLLUMINA

A COLLOIDAL ALUMINIUM HYDROXIDE FOR HYPERACIDITY, GASTRIC INEFFICIENCY AND INTESTINAL STASIS.

A neutral and salt-free preparation which absorbs excess acid in the stomach without giving rise to the evolution of gas which follows the older forms of treatment. It does not depress the acid index of the gastric juice sufficiently to interfere with normal digestive function.

COLLOZIN

A COLLOIDAL ZINC HYDROXIDE FOR ECZEMA, URTICARIA AND PRURITUS.

Collozin spreads better than other zinc preparations, and hence there is a greater percentage of the skin in actual contact with the active constituent. It is valuable as a lotion in various skin diseases, such as acne, eczema, pruritus, psoriasis, urticaria, and similar conditions, and is especially recommended as a sunburn lotion.

Issued in 4-oz., 8-oz., 16-oz., and 80-oz. bottles.

Full particulars may be had on application to—

THE SUPERIORITY OF COD LIVER OIL AS A CURE FOR RICKETS

Leading Authorities have proved by the most painstaking researches that:

A certain number of D-vitamin units in the form of Cod Liver Oil is far more effective in the treatment of human Rickets than the same or even double the number of these units in the form of irradiated Ergosterol.

Read what Professor E. Poulsson says on the subject in his recent paper "On the Action of Cod Liver Oil and Irradiated Preparations in Rickets", published by the State Vitamin Institute in Oslo.

This paper may be obtained free by post on application to the State Vitamin Institute.

The world-renowned Norwegian Cod Liver Oil has always been noted for its high quality. Exported under control of the Norwegian State.

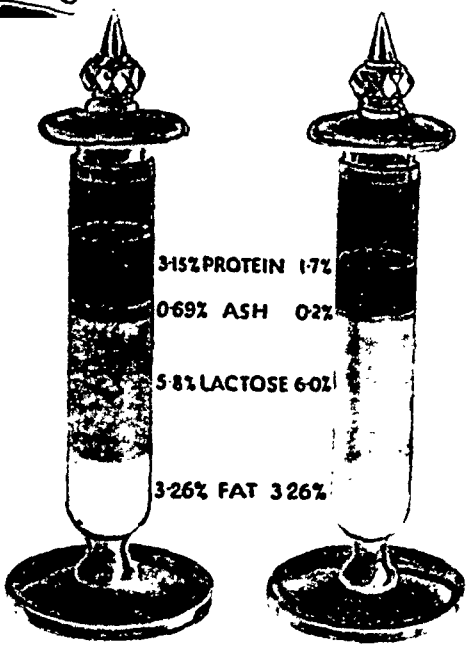
BETTER MILK FOR BABIES

FACTS ABOUT
LACTOGEN



LACTOGEN—diluted by weight with 6½ parts of water.

LACTOGEN MATERNAL MILK

BREAST MILK—Average composition taken from "Principles of Human Physiology"—Starling.

Correct Balance

Lactogen is not merely a dried milk powder, but milk, scientifically modified to provide the physiological balance required by the human infant. The addition of carbohydrate to the cream-enriched fresh milk corrects the natural deficiency and reduces the excess of protein.

The normal constituents of maternal milk are thus furnished in correct proportion. Lactogen is prepared to this unvarying composition:—

Fat	24.5 per cent.
Protein	23.7 " "
Carbohydrate	43.6 " "
Mineral Salts	5.2 " "
Moisture	3.0 " "
Caloric Value	143 calories per oz.

A Medicinal tablespoonful of Lactogen weighs 0.2 ozs. and furnishes 28.6 calories. To ensure correct and uniform feeds, a hygienic aluminium measure of this equivalent is provided with each tin of the food.

Lactogen is neither a new nor untried product. First introduced in Australia, it has for many years enjoyed a large sale in overseas countries.

VOTIVE CROWN OF THE VISIGOTHS WHO WERE DOMINANT IN SPAIN FOR NEARLY THREE CENTURIES.—The Teutonic occupation has left its mark upon modern Spain—upon its people by intermarriage and in its laws by the incorporation of some elements from Visigothic codes. Euric (died 484), the first Visigothic King of Spain, made their first written code. Codification was continued by some among his successors, the body of law known as the *Leges Wisigothorum* being the result. In the middle of the seventh century Romans, Spaniards and Goths were brought under one system of law. Of Visigothic art little survives except very beautiful jewellery and goldsmith's work. The Teutons built many palaces, churches and monasteries, but it is not easy to trace the Visigothic characteristics. The splendid votive crown here reproduced is one of a number still in existence. They were royal offerings and were suspended in churches, before the altar. The crowns are of gold and are set with sapphires, pearls and small garnets or discs of ruby glass. The one here figured bears the name of King Reccesvinth (649—672).

Observations
ON
FRACTURES OF THE NECK OF THE FEMUR*
BY
SIR ROBERT JONES, BT., K.B.E., C.B., F.R.C.S.

Fracture of the neck of the femur is a grave condition; and gives rise to considerable anxiety both to practitioner and to surgeon. No one can accurately foretell the final result as to either bony union or good function. Further, there is no fracture which has been more neglected. There are thousands of students and practitioners who have never had an opportunity of following a case through its various phases from beginning to end, but we have all seen several instances of the inefficiently treated and neglected case. Such fractures are very rarely treated in teaching hospitals; as a rule, they are sent off to Poor Law institutions because of scarcity of beds and the inevitably prolonged course to recovery. This has given rise to quite an unnecessary spirit of pessimism. We are apt, in the case of the aged, to conclude that the end-result is almost inevitably bad, and that if they escape death from chest complications they are fortunate and should be grateful, no matter how crippled they remain. But this is not all, for adequate treatment is withheld on the plea that it adds to the risk of death. I hope to show how wrong it is to take this view, and that we have every right, with modern knowledge, to expect a good functional result in a large majority of cases in spite of old age and feebleness. Even in the neglected case surgical procedures are at our command whereby pain and severe crippling can be overcome.

EPIPHYSEAL STRAINS IN THE ADOLESCENT

There are three types of cases with which I will deal, and each has its own special clinical importance. The first includes injury to the epiphysis in early adolescence, and is sometimes known as slipped epiphysis or traumatic coxa vara, first described by Royal Whitman. It is associated especially with school age, and is due to strain. It is not uncommon, and should not be overlooked in its early stage. The condition consists of a partial or complete separation of the epiphysis, a fracture through the neck, or a fracture involving both neck and epiphysis. Partial separation of the epiphysis is the more usual variety.

For diagnostic purposes I will describe a typical case of partial and of complete separation of the epiphysis. A boy while playing football attempts to turn suddenly, and feels a sharp pain and suffers disability at the hip. He hobbles off the field, and after resting a short time walks back to school and rests. If the surgeon is sent for he will find the movements fairly free in the direction of flexion, extension, and adduction; the rotations are distinctly painful and so is abduction, which is limited. The measurements of the limb are normal. For ten or twelve days he rests and later begins his games, when another strain reproduces his symptoms, and games are prohibited for the rest of the term. During exercise something again "gives" in the hip, and he has to be carried off to bed. The limb is now shortened about half an inch, and a partial, or complete, separation of the epiphysis will be found. The *x*-ray examination shows the femoral head in position and the femoral neck displaced upwards.

In another type the injury is much more severe, and the disability more pronounced and lasting. Here we find we are dealing with a fracture of the neck, with a complete separation of the head, or with a combination of both.

There is a third type, which completes the clinical group. A youth strains his hip and is slightly disabled for a day or two. As the weeks pass he complains of an increasing lameness and stiffness of the hip. His symptoms closely resemble a starting arthritis. There is a limitation of movement in all directions, shortening of the limb, and elevation of the trochanter above Nelaton's line. A skiagram shows a coxa vara of the epiphyseal type in which the neck participates. The slight injury has partly separated the epiphysis, and under the strain of body weight coxa vara occurs, associated with traumatic arthritis.

We may assume, therefore:

(*a*) That a single strain, or a succession of strains, of the hip-joint in adolescence, if followed by disability, limited rotations, and limited abduction, denotes a partial epiphyseal separation.

(*b*) If a strain completely disables the patient and is accompained by elevation of the trochanter complete separation of the epiphysis, or fracture of the neck, is suggested.

(*c*) If a slight injury be followed by a limp, rigidity, and shortening of the limb, developing slowly, we are probably dealing with a traumatic coxa vara following a partial separation of the head, and exhibiting signs of a traumatic arthritis.

The importance of an early diagnosis cannot be too strongly stressed; whichever type the case may be it will readily respond to treatment. A neglected coxa vara may leave a deformed and disabled hip. It should always be remembered that coxa vara may follow twist or strain, especially if the strain is repeated, even if the radiograph is at first negative.

Treatment

If the *x*-ray examination is negative the limb should be fixed for a few weeks in a splint or plaster. Abduction is not necessary. If the epiphysis has slipped, plaster should be applied in an abducted position for at least three months, and when walking is allowed body weight should be transmitted to a calliper splint. If arthritis is added to coxa vara, plaster and abduction should be continued for at least six months. The abduction should not be too forcible and extreme, as distortion may occur to the softened head of the femur.

FRACTURES OF THE NECK OF THE FEMUR IN THE AGED

A point that distinguishes fractures in the aged is that they occur usually with but little trauma, and often by a cross breaking or indirect force—for example, when a fracture occurs in bed or in getting out of bed. This is readily explained by the facts that in the aged the bone is atrophied and brittle, and the muscular control lessened, while the angle formed by the neck and shaft is more acute, sometimes approaching a right angle. I shall refer only to two sites of fracture: one occurring near the head (subcapital), often referred to as "intracapsular," and the other near the trochanter, formerly called "extracapsular." The subcapital is the fracture which has always been, and still is, anathema to our profession.

In the aged, even under the best treatment, non-union is often observed, and it is found in practically all neglected cases. Although bony union is essential to a perfect result we may meet with a fair degree of function in a case with fibrous union, and with poor function in a bony mal-union. The explanation of this will be apparent later. The main reason for non-union is due here, as in other fractures, primarily to imperfect apposition, and also to the fact that the neck of the bone throws out a callus never exuberant. To this we may also add its

* Lecture-demonstration before the Nottingham Medical Society, February 25th, 1931.

sparse blood supply. The chief sources of supply are: (1) a vessel entering the upper part of the neck just above the great trochanter; (2) a vessel on the under side of the neck; (3) a small vessel at the internal side of the epiphysis of the head; (4) a vessel entering through the ligamentum teres, which is usually obliterated in early childhood. There is a network of small vessels surrounding the epiphyseal line which practically disappears in the aged.

In deciding upon treatment it is well to study the deformities found in the old neglected case. In this way we are taught what to avoid. This method of observation will also help us in dealing with fractures of other bones.

A neglected case will enter the out-patient room usually with a crutch and a stick. He is very lame, and walks with pain. He saves the injured limb from heavy pressure, his foot being turned out. Examination reveals a real shortening, from an inch and a half upwards; the practical or apparent shortening is more, due to elevation of the pelvis. The limb is adducted, and abduction is very limited, while rotation inwards cannot be performed. There is usually about 40 or 50 degrees of flexion deformity; therefore all movements of the hip are limited. Very often the tendo Achillis is shortened.

This description covers most cases displaying very gross and very unnecessary deformity, which should never be allowed to occur even in cases of non-union. To prevent these deformities, therefore, the recent fracture should be treated with the limb extended, abducted, and rotated inwards, and the foot should be kept at right angles. If the limb be placed and kept in this position for a sufficiently long period, such deformity as I have described need never occur. This is the first and most important fact I wish to emphasize.

The Recent Case

Diagnosis.—An aged person falls or strains his hip and is quite disabled. The limb is adducted, shortened, and externally rotated, and cannot voluntarily be lifted. There is pain on pressure over the femoral head below Poupart's ligament, and the ilio-tibial band is relaxed. A radiograph confirms the diagnosis of fracture of the neck of the femur.

Anatomy of the Deformity.—The femur is displaced upwards by the glutei, rectus femoris, adductors, and hamstrings; inwards by the adductors and quadratus femoris, and is rotated outwards by the weight of the limb in the recumbent position.

Position of Fractured Ends.—The face of the fracture of the outward fragment looks forwards. The radiograph will show the position of the fracture, whether subcapital or at the base of the neck. Non-union is much more apt to follow the subcapital than the basal fracture. The treatment of both varieties is identical. The fracture may be impacted. If left alone and not fixed it usually becomes disimpacted in a few days. When the impaction has been very firm it sometimes happens that the patient has walked upon the limb immediately after the accident, and has been able to lift the limb from the bed. I have seen several such cases.

Mechanical Treatment of the Recent Case.—If there is impaction we have to decide whether the fragments shall be disengaged. This depends entirely upon the alignment. Impaction seldom connotes good apposition, and therefore it should not be allowed to hold, except in rare cases. If the impacted limb is shortened we may be sure the fractured ends are not in alignment; if there is fixed external rotation or adduction it is obvious that reduction must be undertaken. An impaction should not be interfered with when apposition is good and the limb is not rotated outwards, adducted, or shortened. Such an impaction is rare indeed. The aim of treatment is to secure good alignment, complete abduction, and internal rotation. If we fail by these means to obtain union we shall certainly have averted the possibility of ultimate gross deformity, and achieved a fair functional success. The abduction treatment may be carried out by means of a splint or by plaster. The splint I have advocated in the past is a double abduction frame reaching only to the umbilicus, with a groin strap to allow of fixed extension. In exceptionally fat people I think this is still the best method, but for the routine case I am convinced that the plaster method described by Royal Whitman is the safest and most efficient procedure. When we speak of the abduction treatment we refer to the method originated and first described by Royal Whitman, who has placed this technique on a scientific basis. Many of us have abducted the femur, but Whitman has shown us precisely what to do and the reasons for doing it. A femur may be abducted without the fractured ends being brought into apposition, and the results will be disappointing. Whitman states that if under anaesthesia the upward displacement of the shaft be reduced by manual traction on the limb, combined with slight inward rotation, the fragments would lie in the same plane, and abduction to the normal limit would secure the fragments in close apposition, while the tension on the capsule incidental to abduction would prevent displacement and force the fragments into direct contact, which in fractures of the cervical type is essential to repair. The security assured by bony contact and capsular tension will be further augmented by the contact of the trochanter with the side of the pelvis, while in the subcapital variety the fracture line will be included within the acetabulum. This secures the relaxation of the muscles which cannot be controlled by any other non-operative method. Whitman's contribution, therefore, consists of the correct apposition of fragments (which, in this fracture more than in any other, is positively essential) followed by fixation in position by abduction. Any splint which succeeds in holding these fragments in position would suffice, but none will compare with plaster-of-Paris, which can be relied upon to be effective, provided it is properly applied. It is necessary to emphasize this, for the correct technique is too often ignored. There is no time to enter into elaborate detail of the method of applying the plaster spica, although it must be mastered if it is to be both comfortable and efficient. Properly applied there need be no fear of pressure sores.

Reduction and Fixation.—The length of the two limbs should be measured, and the broken limb should be restored to its normal length by manual traction, and then rotated inwards. The limb should next be abducted. The abduction should be complete, and, as the angle varies in different people, information is gained by noting the amount of normal abduction on the sound side. The angle is usually about 40 degrees. If the hip sags it should be lifted, and I find it useful before abducting the limb to make traction outwards. This disengages the overlapping which is sometimes present. The patient is now placed on a pelvic support and manual traction is maintained on the limb, which should be rotated inwards. If the rotation is adequate the lesser trochanter should be barely seen in the radiograph. The thigh should be fully extended, or even slightly over-extended, and the knee kept slightly bent. Subsequent stiffness is more rapidly recovered from if the knee is not kept in full extension. The plaster should be continued sufficiently high and well rubbed in to grip the pelvis and secure adequate leverage, and should extend to, and include, the foot. While the

plaster is being applied both legs should be abducted in order to control the pelvis, otherwise the abduction may be complicated by pelvic obliquity. The foot should be kept at right angles. In transcervical and subcapital fractures the plaster support around the hip of the aged should be maintained for six months, but in three months the knee may be freed and put through its range of movements. Pillows may be placed below the head and shoulders, and the head of the bed may be raised eight or twelve inches. This will obviate any danger there may be in cases threatened by chest complications. The dorsal position of the patient can occasionally be changed to ventral or semilateral without in any way jeopardizing the correct alignment of the fractured ends. It is a relief to the patient sometimes to be placed on his face.

After-care treatment should be attentively conducted. The bowels should be carefully regulated, and for the first few days a fluid diet should be prescribed. Beef tea, broths, arrowroot made with water, should form the principal food. Large quantities of milk, which as we know becomes solid in the stomach, should not be given. In this way the abdominal disturbances, so awkward when they arise, will be avoided. *X*-ray examination should decide whether union has occurred or not, and if necessary the plaster should be continued beyond the six months. When the plaster is removed the patient should lie in bed for a few days, keeping his limb abducted, while massage and gentle passive movements may be given. No weight-bearing on the fractured limb should be allowed ; a calliper should be carefully fitted so that weight-bearing is taken from the ischial tuberosity and not from the neck of the femur. Whether bony union has taken place or not freedom of abduction should be the aim. If fixed adduction is allowed to occur the functional result will be very imperfect. If these principles of reduction and fixation are observed, whether bony union occurs or not, we may expect a fair functional result. In other words, much of the disability which we encounter in old cases will be considerably lessened if we prevent a fixed adduction.

BASAL FRACTURE IN THE YOUNGER ADULT

The so-called extracapsular or basal fracture, commonly met with in the younger adult, should be treated as that of a fracture in the aged. Here, however, bony union is to be expected as a routine, and the plaster fixation need never exceed three months. In six weeks the knee can be freed, and when walking is begun it is rarely necessary to wear a calliper splint. It is essential that the power of abduction should be preserved. Non-union is likely to result even in " extracapsular " cases if treatment is carelessly conducted.

DISCUSSION OF ABDUCTION METHOD

It is useful to know what percentage of bony union may be expected in the aged treated by the abduction method. Perhaps the most complete recent statistics are those of Lofberg, published in 1927.[1] The number of cases treated was 264—88 males, 176 females ; 78 per cent. of the patients were over 55 years of age ; the youngest was 17, the oldest 95. Of the cases, 172 were intracapsular ; in these bony union and good function were obtained in 76 per cent. In the 92 extracapsular, bony union and good function resulted.

A full abduction is difficult to obtain without anaesthesia ; yet in the figures supplied by Lofberg the majority of the fractures were reduced without general anaesthesia. Further, the period of fixation was limited to eight weeks. Willis Campbell's figures are even more favourable. Scudder says: " The overwhelming accumulation of evidence that the abduction treatment is highly efficient in securing bony union has raised the most neglected of all fractures to the first place in the therapeutic scale." One may offer a favourable prognosis both as to life and function in about 75 per cent. of all cases treated by the abduction method if it is effectively applied.

ARTIFICIAL IMPACTION

Cotton advocates artificial impaction of the femur in good position. Having reduced the fracture by traction and internal rotation he places a pad of felt over the great trochanter and strikes one or more blows with a wooden mallet weighing about 8 lb. Counter-pressure is put on the sound side of the pelvis. The hammering is considered to be successful when the neck appears to be firm and the limb does not fall back into eversion. The limb is then placed in abduction. I have had no personal experience of artificial impaction, and cannot, therefore, criticize it, but it is obviously very necessary to reduce the fracture completely before using the mallet, or only mischief will result. If alignment and apposition are good, is there much or anything to be gained by artificial impaction? Willis Campbell, however, whose experience is extensive, regards it as a distinct addition to the Whitman technique, and claims 89 per cent. of bony union. The method may be of definite service in cases which have been unreduced for some weeks. Reduction should, of course, be first effected and the limb placed in abduction.

OPEN OPERATIONS ON THE RECENT CASE

In view of what has been said as to the results of the abduction method, which is accompanied by only a 5 per cent. mortality, a very strong case should be presented before resorting to the risks of an open operation in the aged. It should never be needed in the so-called extracapsular fracture, which almost invariably unites. In my experience an open operation on a recent case of subcapital fracture of the neck should be a very rare event. It adds considerably to the mortality, and should never be undertaken except by very expert surgeons who have a sound practical knowledge of the mechanical methods at their disposal. Although I have never operated upon a recent case, I have seen many unhappy after-results.

THE OLD UN-UNITED CASE

The deformities here, as stated elsewhere, are flexion of the thigh, adduction, rotation outwards with marked functional disability, and generally pain. What should we do in such cases? In the old and feeble we should resist the temptation to practise any procedure accompanied by great shock. We should aim at relief of pain by posture and mechanism, and avoid prolonged recumbency. The adduction—always the evil factor—should be corrected as far as possible, and the hip should be fixed by a plaster spica. The spica should be light, and need not extend below the knee. Two or three weeks is generally sufficient to bring about ease and comparative comfort. Graduated walking exercise should then be practised. Any stiffness of the knee or ankle should be overcome by gentle passive movements assisted where possible by physiotherapy. When a few weeks have passed a weight-bearing ambulatory splint, such as a calliper, should be worn for an indefinite period. By abducting the limb we minimize the cross-breaking strain and release the hip from adhesions which, even more than chronic arthritis, give rise to constant pain on movement. We have often met with patients who, refusing to rest, have obtained considerable relief from gentle manipulation.

There is another type of " intracapsular " fracture in old and infirm people who have but little pain when they

limit their activities, but feel weakness and pain when they have walked a little distance. These cases are best treated by a weight-bearing splint, and the patients should be taught exercises for muscle development in the recumbent position, so that their condition is not complicated by the incidence of body weight. Many very old people will sometimes consult us because they have a short leg and limp badly, and cannot walk long distances, but have no pain. It is obvious in such cases that, apart from regulating the unequal length of the limbs, nothing should be done of a drastic character. A firm flannel spica bandage round the hip gives a sense of stability and strength. Even a calliper may not be needed, as there is no pain to be relieved, and further shortening is unlikely.

A certain number of patients, however, are sufficiently strong and disabled to warrant more drastic measures. The operative procedures which can be adopted may be divided into four main classes.

(*a*) Freshening and fixing the bones in good position. This entails exposing the fractured ends, removing all fibrous material, and opposing the freshened ends. They may be kept in apposition by the abduction method with or without pegs.

(*b*) Reconstruction of joint, as practised by Brackett or Royal Whitman.

(*c*) Transference of weight-bearing, such as modification of the bifurcation operation, devised originally by Lorenz for the treatment of unreducible congenital dislocation of the hip.

(*d*) Removal of the head of the femur.

The Pegging Operation.—If bone is employed it should be about half an inch in thickness. An incision is made over the front of the joint, the fibrous tissue dissected away, and the ends of bone freshened. The freshened ends are placed in apposition. The base of the trochanter is then exposed and a hole drilled along the neck into the head. With the fragments in position the bone peg is hammered into the tunnel. The correct alignment of the peg can be verified by an examination through the anterior wound.

Whitman's Operation.—This operation aims at removing the femoral head and adding to the length of the neck by removing the portion of the trochanter with muscle attached and by fixing it on the shaft as low as possible. The reconstructed neck is placed in the acetabulum and the limb fixed in abduction.

Brackett's Operation.—In this operation the head is retained in its socket. The tip of the trochanter is detached and the fractured surfaces are freshened, the trochanteric end made convex to fit into a concavity chiselled into the head. The portion removed from the trochanter with tendinous attachments is fixed below.

The Bifurcation Operation (*see Fig.*).—This operation can be employed for un-united fracture in the old. Osteotomy of the femur is performed usually just below the lesser trochanter, and the limb is abducted, the lower end being driven inwards so that it rests on the pelvis just below the rim of the acetabulum.

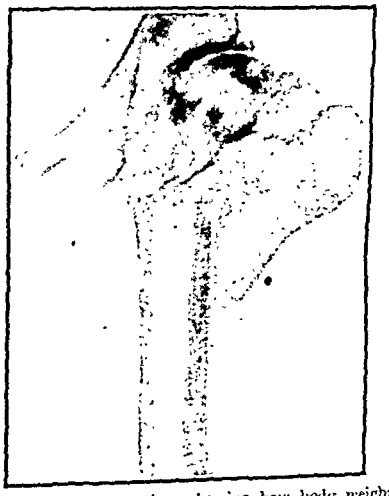
Removal of the Head of the Femur.—This can be performed through an anterior or a posterior incision. It is not always as easy an operation as it sounds. After the removal of the head the hip should be kept abducted for three or four weeks.

The Choice of an Open Operation

Let us remember that any reconstructive operation in the old and feeble, if it involves the exposure of the hip-joint, is a serious undertaking, and is accompanied by considerable shock. Stability and freedom from pain should be the primary objects, and if these be attained the patient is more than satisfied. A stiff joint even, which will enable the patient to walk without discomfort, and with but little risk, is preferable to any reconstructive effort which aims at movement but endangers life. I do not think there is much to choose between the reconstructive operations devised by Brackett and Royal Whitman. Neither of them is inviting in old people with subcapital fractures. Brackett preserves the head; Whitman removes it. Brackett endeavours to bring about union, and there is necessarily the risk of failure; Whitman places the neck into the empty acetabulum. In both operations abduction is necessary, and I should have feared a liability to displacement on adduction. Both of these distinguished authors, and others, have reported successful cases, but I have had no personal experience of either method, nor of the reconstructive operation practised by Albee. On several occasions I have removed the head of the femur with moderate success. Pain is nearly always relieved, and, provided the limb is kept abducted, there is improvement of function.

The Bifurcation Operation

I feel satisfied that for an open attack in the aged the bifurcation operation has many advantages. The joint is not interfered with, shock is negligible, and the procedure occupies only a few minutes. Body weight is deflected directly on to the femur without the intervention of the joint. A four-inch incision is started at the base of the trochanter and carried downwards. The femur is divided almost transversely just below the lesser trochanter. The upper end of the lower fragment is pushed inwards and then directly upwards until it impinges against the pelvis at the lower border of the acetabulum. The limb is kept in moderate abduction in plaster. It is an incredibly simple procedure, and the result completely changes the patient's outlook, for stability is combined with movement. The same operation will relieve the distressing symptoms of advanced osteo-arthritis in old people. Fixation in very slight abduction should last three months.



The bifurcation operation, showing how body weight is deflected from the un-united fracture of the neck on to the shaft.

Reconstructive operations can be performed with comparative safety in young and middle-aged adults, and the arguments I have used in dealing with the aged do not apply here. The type of reconstruction must depend largely upon the character of the fracture, but where it is possible a bone peg, as practised by Albee, offers the best functional success. A surgeon who has allowed deformity to occur should not operate unless he has learned the technique and principles of the abduction method.

COMMENTARY

Operations in old patients, therefore, take a very secondary place compared with primary mechanical treatment. The cases left for operation are usually neglected ones. Un-united and mal-united fractures occurring in the virile—for which reconstructive operations are needed—*should* very rarely occur if subjected to the abduction method. But we cannot be astonished at the unsatisfactory results in fractures of the neck generally when a spirit of pessimism and *laissez-faire* governs our treatment of the aged. In a modern textbook, speaking of "extracapsular" fractures, the author says: "They will get well anyhow *under good or bad treatment.*" This is an excuse for carelessness which may result in tragedy. We should further realize that the aged, subjected to appropriate mechanical fixation, are less in danger of death than when their fractures are untreated.

We need only refer to the report of the British Medical Association's committee of inquiry into the treatment of fractures, published twenty years ago, to realize how startling were the failures in fractures of the neck of the femur. Of twenty cases occurring in patients between the ages of 26 and 45, only six good functional results are reported; in thirty patients between 45 and 60, only eight good results, and in thirty-six over 60, only five. These were the days of Liston's splint and sand-bags, before it was realized that it was essential and possible to reduce the displacement. But even so late as 1928 Katzensteen reported to the Surgical Society of Berlin the results of 169 cases of transcervical fractures treated by conventional methods, with only 11.5 per cent. of good results. This is an interesting commentary on conventional methods, which have not improved in fifty years. The profession owes a deep debt of gratitude to Royal Whitman for his persistent insistence in standardizing the abduction method.

In conclusion, may I again venture to urge that no student should leave hospital without being taught the modern method of treating fractures of the neck of the femur.

SPINAL ANAESTHESIA

A STUDY OF 250 CONSECUTIVE CASES*

BY

A. WILFRID ADAMS, M.S., F.R.C.S.

SENIOR ASSISTANT SURGEON, BRISTOL ROYAL INFIRMARY; SURGEON, BRISTOL CHILDREN'S HOSPITAL

Without ether and chloroform the amazing expansion of possible surgical procedures in the last half-century would not have occurred. Recently, efforts have been made to restrict the action of paralysing agents to the nerves which alone are responsible for giving offence, and to avoid a generalized toxaemia. The congregation of the spinal nerves in the lower part of the thecal tube renders them susceptible to a suitable drug injected into the cerebro-spinal fluid. Rapid and complete anaesthesia ensues, lasting for more than an hour. Further, it is obtained without the tedium of local infiltration methods and the sodden state of the tissues associated with them.

Formerly, using the spinal route, I was alarmed to find patients pale and sweating, with dilated pupils, and complaining of excessive weakness. Although none died, the anxiety was intolerable. However, reports on thousands of successful cases from various sources[1 2] filled me with admiration and a great curiosity to find what were the technical requirements in order to obtain a satisfactory result. Great praise is due to Pitkin[3] for revealing the underlying anatomical basis and physiology of spinal anaesthesia. He has evolved a safe injection called spinocain; novocain is the essential constituent, but its influence is controlled by other ingredients.

ACTION OF SPINOCAIN

The profound lowering of vitality in my former cases was due to extensive palsy of the sympathetic fibres, which leave the cord with the issuing dorsilumbar nerves (Fig. 1). This Pitkin combats by a preliminary subcutaneous injection of ephedrine. Further, to control the spread of spinocain, he mixes it with gliadin, a mucilage from wheat starch, which is viscous and which arrests ordinary diffusion; the addition of alcohol lightens it. Pitkin likens its behaviour, on entering the thecal tube, to "a bubble floating in a spirit level." Thus, with the spine horizontal, it will tend to produce a paraplegia up to the segment of the cord opposite the level of injection. By tilting the tube tail end upwards only the parts supplied by the lumbo-sacral nerves are paralysed; by tilting the spine head upwards the paraplegia extends to the chest, and if the head is raised sufficiently, will implicate the phrenic nerves. The physics of spinocain needs to dominate the anaesthetist completely if disaster is to be avoided.

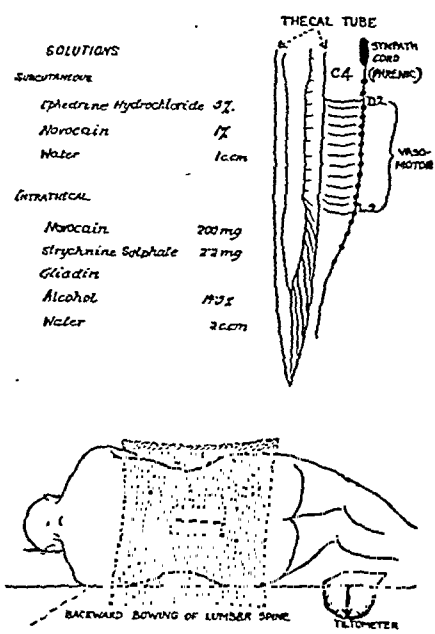

FIG. 1.—Pitkin's solutions. Diagram of spinal and sympathetic nerves and posture of patient.

If, while inducing anaesthesia, anxiety arises as to undue ascent of the paralysis or excessive lowering of vitality, or both, there appears one of the outstanding advantages of spinocain, for when such dangers threaten the method of combating both is identical. The Trendelenburg posture sends blood to the vital centres, and, thanks to the lightness of the solution, any remaining unfixed spinocain travels back to the harmless lumbo-sacral levels. Posture determines the distribution of the

* Abstract of a lecture given to the Bristol Medico-Chirurgical Society, January, 1931.

limit their activities, but feel weakness and pain when they have walked a little distance. These cases are best treated by a weight-bearing splint, and the patients should be taught exercises for muscle development in the recumbent position, so that their condition is not complicated by the incidence of body weight. Many very old people will sometimes consult us because they have a short leg and limp badly, and cannot walk long distances, but have no pain. It is obvious in such cases that, apart from regulating the unequal length of the limbs, nothing should be done of a drastic character. A firm flannel spica bandage round the hip gives a sense of stability and strength. Even a calliper may not be needed, as there is no pain to be relieved, and further shortening is unlikely.

A certain number of patients, however, are sufficiently strong and disabled to warrant more drastic measures. The operative procedures which can be adopted may be divided into four main classes.

(*a*) Freshening and fixing the bones in good position. This entails exposing the fractured ends, removing all fibrous material, and opposing the freshened ends. They may be kept in apposition by the abduction method with or without pegs.

(*b*) Reconstruction of joint, as practised by Brackett or Royal Whitman.

(*c*) Transference of weight-bearing, such as modification of the bifurcation operation, devised originally by Lorenz for the treatment of unreducible congenital dislocation of the hip.

(*d*) Removal of the head of the femur.

The Pegging Operation.—If bone is employed it should be about half an inch in thickness. An incision is made over the front of the joint, the fibrous tissue dissected away, and the ends of bone freshened. The freshened ends are placed in apposition. The base of the trochanter is then exposed and a hole drilled along the neck into the head. With the fragments in position the bone peg is hammered into the tunnel. The correct alignment of the peg can be verified by an examination through the anterior wound.

Whitman's Operation.—This operation aims at removing the femoral head and adding to the length of the neck by removing the portion of the trochanter with muscle attached and by fixing it on the shaft as low as possible. The reconstructed neck is placed in the acetabulum and the limb fixed in abduction.

Brackett's Operation.—In this operation the head is retained in its socket. The tip of the trochanter is detached and the fractured surfaces are freshened, the trochanteric end made convex to fit into a concavity chiselled into the head. The portion removed from the trochanter with tendinous attachments is fixed below.

The Bifurcation Operation (see Fig.).—This operation can be employed for un-united fracture in the old. Osteotomy of the femur is performed usually just below the lesser trochanter, and the limb is abducted, the lower end being driven inwards so that it rests on the pelvis just below the rim of the acetabulum.

Removal of the Head of the Femur.—This can be performed through an anterior or a posterior incision. It is not always as easy an operation as it sounds. After the removal of the head the hip should be kept abducted for three or four weeks.

The Choice of an Open Operation

Let us remember that any reconstructive operation in the old and feeble, if it involves the exposure of the hip-joint, is a serious undertaking, and is accompanied by considerable shock. Stability and freedom from pain should be the primary objects, and if these be attained the patient is more than satisfied. SPINAL ANAESTHESIA

A STUDY OF 250 CONSECUTIVE CASES*

BY

A. WILFRID ADAMS, M.S., F.R.C.S.

SENIOR ASSISTANT SURGEON, BRISTOL ROYAL INFIRMARY; SURGEON, BRISTOL CHILDREN'S HOSPITAL

Recently, efforts have been made to restrict the action of paralysing agents to the nerves which alone are responsible for giving offence, and to avoid a generalized toxaemia. The congregation of the spinal nerves in the lower part of the thecal tube renders them susceptible to a suitable drug injected into the cerebro-spinal fluid. Rapid and complete anaesthesia ensues, lasting for more than an hour. Further, it is obtained without the tedium of local infiltration methods and the sodden state of the tissues associated with them.

Formerly, using the spinal route, I was alarmed to find patients pale and sweating, with dilated pupils, and complaining of excessive weakness. Although none died, the anxiety was intolerable. However, reports on thousands of successful cases from various sources[1,2] filled me with admiration and a great curiosity to find what were the technical requirements in order to obtain a satisfactory result. Great praise is due to Pitkin[3] for revealing the underlying anatomical basis and physiology of spinal anaesthesia. He has evolved a safe injection called spinocain; novocain is the essential constituent, but its influence is controlled by other ingredients.

ACTION OF SPINOCAIN

The profound lowering of vitality in my former cases was due to extensive palsy of the sympathetic fibres, which leave the cord with the issuing dorsilumbar nerves (Fig 1). This Pitkin combats by a preliminary subcutaneous injection of ephedrine. Further, to control the spread of spinocain, he mixes it with gliadin, a mucilage from wheat starch, which is viscous and which arrests ordinary diffusion; the addition of alcohol lightens it. Pitkin likens its behaviour, on entering the thecal tube, to "a bubble floating in a spirit level." Thus, with the spine horizontal, it will tend to produce a paraplegia up to the segment of the cord opposite the level of injection. By tilting the tube tail end upwards only the parts supplied by the lumbo-sacral nerves are paralysed; by tilting the spine head upwards the paraplegia extends to the chest, and if the head is raised sufficiently, will implicate the phrenic nerves. The physics of spinocain needs to dominate the anaesthetist completely if disaster is to be avoided.

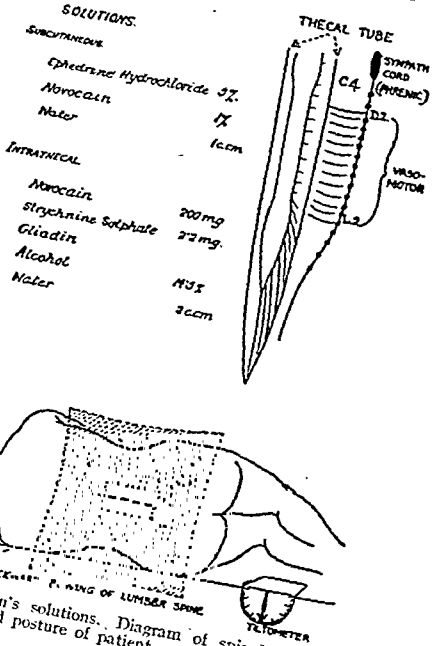

FIG. 1.—Pitkin's solutions. Diagram of spinal and sympathetic nerves and posture of patient.

If, while inducing anaesthesia, anxiety arises as to undue ascent of the paralysis or excessive lowering of vitality, or both, there appears one of the outstanding advantages of spinocain, for when such dangers threaten the method of combating both is identical. The Trendelenburg posture sends blood to the vital centres, and, thanks to the lightness of the solution, any remaining unfixed spinocain travels back to the harmless lumbo-sacral levels. Posture determines the distribution of the

* Abstract of a lecture given to the Bristol Medico-Chirurgical Society, January, 1931.

spinocain, and with the patient on his side, the exposed spine, in a case with a relatively broad pelvis, is seen to slope down somewhat towards the table top. This nullifies the first few degrees of upward tilt, and must be allowed for in reading the tiltometer (Fig. 3).

In all but a few cases, less than ten of my series of 250, I have administered Pitkin's light spinocain solution.

STATISTICS OF THIS SERIES

It must be noted with the following numbers, first, that they relate to ordinary surgical practice and are given without selection of favourable surgical subjects. Secondly, they include cases of the "beginner."

Number of cases, 250.
Successful anaesthesia, 221.
Failures, partial or complete, 29.
Ages varied from 3 to 81, with 44 years as the average.
Dose varied from 1/2 to 3 c.cm.
Time consumed in tapping the cerebro-spinal fluid was recorded in 43 cases, and averaged less than a minute (usually half a minute).
Time taken for the development of the requisite anaesthesia was recorded in 180 cases, and averaged eight minutes. This was partly proportional to the height required.

TECHNIQUE

After the application of iodine a perforated, sterile cloth is placed on the back (Fig. 1). The space selected for injection is the third or fourth lumbar, and gapes helpfully if the spine is bowed backwards. The spine should be on a level with the eye of the anaesthetist, who is seated. The preliminary dose of ephedrine is given, combined with the novocain used as a local anaesthetic (Fig. 2), then the skin is pierced with a No. 11 Bard-Parker blade exactly in the mid-line. Through this, the

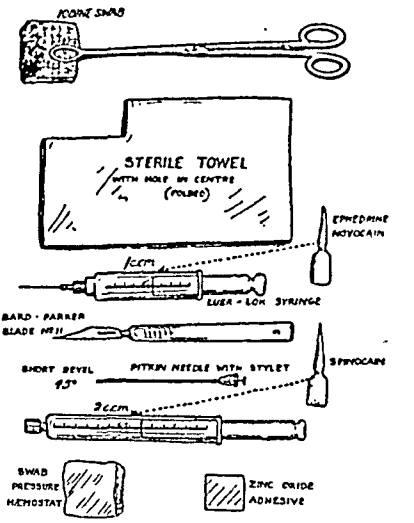

FIG. 2.—Requisite articles in their order of use.

special needle, little larger than that used for ordinary intravenous injection, punctures the theca without the risk of carrying in skin infection. The needle, held with shaft between the index finger and thumb, meets with moderate resistance and penetrates the ligamentum subflavum and then the theca with a snick that is often audible. Being fine and sharp, it makes a neat hole that closes and prevents leakage of cerebro-spinal fluid after withdrawal. This technique is claimed by Pitkin to prevent subsequent headaches. In the exact mid-line (this is apt to be elusive) Pitkin escapes the vertebral veins. I found, among adults, the minimum and maximum distances from skin to dura were 1.75 inches and 3.25 inches respectively. If the surgeon be skilled in this manœuvre with the delicate Pitkin needle, the anaesthetist may be glad to delegate the task to him. Rotation of the needle may be needed to induce the flow of cerebro-spinal fluid when no drops are forthcoming at the first entry of the theca; 2 c.cm. of spinocain are injected slowly after a confirmatory suck-out gives certainty that the needle orifice is still in the cerebro-spinal fluid. The exact time is noted, and in a few minutes the patient is paralytic. A few patients have needed a second injection. Once the required area of the body is anaesthetic, the table is immediately tilted to some degree of Trendelenburg position. Should the operation be a short one, taking about half an hour, the patient must be guarded against further ascent of the spinocain by being maintained in a Trendelenburg position on the way back to bed. The foot of the bed is always kept raised on six-inch blocks for two hours.

DETAILS OF DOSAGE AND CONTROL OF ASCENT

The dosage and tilts required to obtain the different levels of anaesthesia are shown on Fig. 3. When abdominal anaesthesia is sought, the head-piece of the table should be dropped so that the cervical spine droops markedly. This makes the highest point of the spine correspond to the third or fourth dorsal nerve. Since the injection is lighter than the cerebro-spinal fluid, it will not travel beyond this level. After this safeguard the required ascent dorsally is obtained by inclining the table 5 degrees upward on giving the injection. After three minutes a guide as to the speed and level of ascent is obtained by asking the patient to straighten the uppermost leg and by pinching. Further adjustment of the table depends on the response. If paralysis is rising slowly, the table is raised to an angle of 10 degrees. Immediately the level of anaesthesia is adequate, the table is lowered into the Trendelenburg position. Only then the patient is carefully turned on to his back and a small nick made at the upper end of the proposed incision. No other test for surgical anaesthesia is absolutely reliable.

Where the maximum duration of anaesthesia is desired 3 c.cm. are used. For children the scale of doses according to Pitkin has been followed with good results. Table management, as stressed by Featherstone,[4] has an important influence on results. Smooth movements are essential, and sudden jerks and jars must be avoided, for they may induce dangerous vomiting or worse disasters. Owing to the continuity of peritoneal tissues, sensation may be carried from lower to higher regions by pulling on this membrane. Hence, if there is to be manipulation of peritoneum, a higher level of anaesthesia is aimed at than would be sought for an operation on the parietes alone.

COURSE OF OPERATION

A minority complain of some distress in breathing, palpitation, nausea, or even vomiting as the anaesthetic ascends, and, at twenty minutes, the pulse quickens. Thereafter the patient soon becomes quiet and sleepy. Terminal well-being is most cheering to see, and is in marked contrast to the subdued vitality during operation. Recovery occurs in an hour or two; in one case of partial colectomy return of sensibility occurred within fifty-five minutes of injection. At the opposite extreme is a case of double ureteric transplantation where the spinal anaesthetic was still effective at one and three-quarter hours from the start. After-effects have been notably slight,

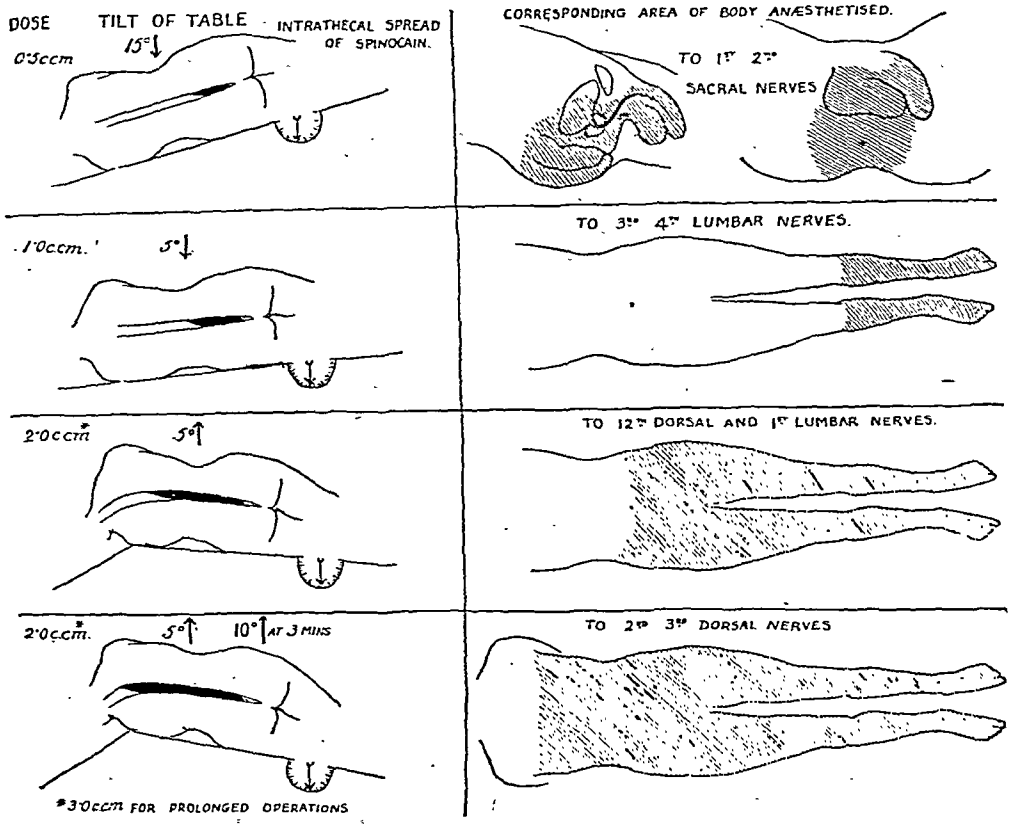

FIG. 3.—Dosage, table-tilting, and distribution of spinocain; corresponding area of body anaesthesia.

apart from vomiting, which is not infrequent, and occasional headaches. The patient may soon take a moderate meal, and next day looks strikingly "normal."

THE IMPORTANCE OF PSYCHANAESTHESIA

A spinal anaesthetic that is locally effective and safe is not necessarily satisfactory. Sometimes the patient's mind is not at ease, and to avoid psychic shock requires the most thoughtful care. Morphine, up to a third of a grain, is given an hour before operation. Basil Hughes[3] recommends avertin as an adjuvant. I find that very light gas and oxygen inhalation is surprisingly effective. Cotton-wool in the ears, and a cloth over the eyes, help the onset of drowsiness. Damping down noise and the clatter of instruments demands unusual degrees of self-restraint from the whole theatre staff.

DETAILED ANALYSIS

The wide scope of the method is shown by the following analysis of the 250 cases dealt with:

Arms—Upper abdomen, 23; lower abdomen, 158; spine, 1; remainder, 68.

Upper Abdominals.—Stomach, duodenum, jejunum, pancreas, kidney, 15; gall-bladder, 8.

Lower Abdominals.—Colectomy, 15; acute intestinal obstruction, 19; prostatectomy, 16; appendicitis, hernia, etc., 108.

Under the heading "Remainder" are included many cases of haemorrhoids, cystoscopies, pyelographies, two major operations on the hip-joint, diaphysectomy of the femur, fractures of thigh and leg, and arthrotomies of the knee and foot. In these cases success is uniform.

Details of the whole series are tedious, so they are given for one category only—namely, colectomy, of which there are fifteen cases with twenty anaesthetics:

Sex	Age	Condition	Operation
F.	53	Gangrenous colitis	Immediate end-to-end union
M.	74	Diverticulitis with abscess	Ditto
M.	65	Colonic stasis	Right hemi-colectomy with immediate side-to-side union
M.	66	Carcinoma of right colon	Hemi-colectomy with immediate side-to side union
F.	64	Ditto	Ditto
M.	50	Ditto	*Ditto*
F.	50	Carcinoma of left colon	Partial colectomy with immediate end-to-end union
F.	49	Ditto	Ditto
F.	67	Carcinoma of left colon with obstruction	Preliminary caecostomy and subsequent resection. Three spinal anaesthetics
F.	54	Ditto	*Ditto*
M.	65	Ditto	Preliminary caecostomy and subsequent resection. Two spinal anaesthetics
M.	57	Carcinoma of rectum	Abdomino-perineal resection
M.	56	Ditto	Ditto
F.	52	Ditto	Ditto
F.	69	Carcinoma coli with vesico-colic fistula	Immediate end-to-end union and suture of the bladder

COMPLICATIONS AT OPERATION

1. *Bony Obstruction to the Needle.*—This proved an absolute bar only in one case, with gross arthritis.

2. *Pain.*—A twinge occurs occasionally, presumably from contact of the needle with one of the filaments of the cauda

equina, and, at the outset of the operation, paraesthesia in the legs and knees may cause the patient to complain.

3. *Pruritus.*—This vexed three patients for variable spells during the operation.

4. *Thirst.*—This often troubles, and is best relieved by a few sips of water.

5. *Nausea and Vomiting.*—Their incidence was noted in 166 patients, of whom 15 per cent. had nausea alone, and 24 per cent. had nausea and vomiting. It is not likely to be over 15 per cent. in operations below the umbilicus if the table is managed cautiously.

6. *Circulatory Anxiety and Shock.*—As a rule, at twenty minutes from the start and proportional to the height of anaesthesia, a marked fall of blood pressure occurs, with pallor and tachycardia. One patient (when accompanying nitrous oxide was being given) ceased breathing and appeared to be dead; artificial respiration was used. The operation was concluded ten minutes later, and, when the skin was tested, spinal anaesthesia was up to the sixth thoracic nerve area. The patient was frail and the subject of acute intestinal obstruction. In the whole series this was the only case that required artificial respiration.

POST-OPERATIVE COMPLICATIONS

1. *Vomiting.*—This was noted in 31 per cent. of cases, but other influential factors, inevitable concomitants of abdominal surgical conditions and operations, must share the blame.

2. *Headache.*—This was investigated in 122 cases; 11.5 per cent. complained, but in only 2 to 3 per cent. was it serious for a few days.

3. *Backache.*—Complaints were few, and were proportional to the amount of needling required to puncture the theca.

4. *Nervous Phenomena.*—Motor and sensory palsy recovered in all instances, starting after sixty to ninety minutes. Ocular palsy involving the sixth nerve supervened in one case only. A man, aged 44, had 2 c.cm. of spinocain for an operation on the os calcis. Internal strabismus appeared seven days later, and lasted three months. Cushing's view on the etiology[6] of this is interesting, and he attributes it to nerve compression by arteries under a swollen pons varolii. One man became stuporous, but, while this followed the use of spinocain for a compound fracture of the tibia, the symptoms are not reported as necessarily attributable to this drug. He was forcibly fed, but was "normal" again on the ninth day.

FAILURES

Although the number (29) of these appears ominous, their incidence was chiefly among the early trial cases. Latterly, failures have been so infrequent as to offer little drawback to the method. They were attributable to a variety of factors:

1. *Inadequate Ascent of the Anaesthesia.*—This occurred in thirteen cases, chiefly from omission of the appropriate slight upward tilt of the spine. One case illustrates the danger of taking, as a guide to the level of ascending palsy, the patient's statements. A man appeared unable to flex his hips when asked to do so two to three minutes after the injection. When the operation was about to begin the abdominal skin was found to be sensitive, so general anaesthesia was employed, and in the struggles that ensued during induction the legs moved freely.

2. *Delayed Ascent of the Anaesthesia.*—If, after a lapse of ten minutes, the lower abdomen is still partly sensitive, experience shows that no appreciable subsequent rise is likely, so additional measures should be used. However, in a few cases, local anaesthesia was added for the line of incision, and, a few minutes later, the spinal anaesthesia was found to have crept up to the required level. This proves the need for lowering the table somewhat into the Trendelenburg position immediately the requisite anaesthesia has been obtained.

3 *Haemorrhage.*—In a boy, where the fourth interspace was used, and in a woman weighing 17 stone, although the needle seemed certainly intrathecal, only blood flowed from it.

4. *Table Mismanagement.*—To the lack of careful and smooth adjustment of the slope of the table seems due the swift death from pneumonia that ensued forty-eight hours after one prostatectomy. Additional general anaesthesia was required. Stomach contents came up into the patient's mouth when he was tilted into the full Trendelenburg position with a sudden jerk.

MORTALITY

When considering this aspect of the subject, it is important to refer to the analysis of statistics, which shows that the cases were not especially selected, and included many major abdominal operations. Fatalities have been grouped in three classes:

(*a*) Attributable to spinal anaesthesia, *nil.*
(*b*) Died during anaesthesia, one.
(*c*) Died subsequently to operation while still in hospital or nursing home, eighteen.

The death under the second heading occurred in a woman, aged 67, suffering from late, acute intestinal obstruction, who was choked by her own vomit. A post-mortem examination revealed colonic cancer and chronic nephritis. Death was obviously due to her disease. The spinocain (2 c.cm.) rose no higher than the sixth dorsal nerve. Of the third group, seventeen deaths followed abdominal operations, and only one after a leg operation. Most of the abdominal operations were for critical conditions, and the death rate did not seem influenced by the spinal anaesthesia.

REVIEW

Reviewing this series, in the light of the experience it affords, the following indications suggest themselves:

1. Where operation is complicated by the presence of cardio-respiratory trouble.
2. In diabetes, jaundice, nephritis.
3. For prolonged operations such as colectomy.
4. In acute intestinal obstruction.
5. For prostatectomy and other bladder troubles. Notable are the associated diminished haemorrhage, good relaxation, and absence of post-operative shock.
6. Operations about the anal sphincter and external genitalia; urethral stricture and male cystoscopy.
7. Major operations on the hip, knee, and ankle; reductions of fractures and dislocations of the lower extremity.
8. In cases where the patient dreads or refuses a general anaesthetic.
9. Especially applicable in a large proportion of cases in infancy and childhood. A child often resents the prick of a needle less than the loss of touch with the world and the suffocative sensations associated with general anaesthesia.
10. Especially applicable in the second half of life. Their experience of life helps older patients. They are less apprehensive than young adults, and more rapidly resign themselves with confidence to the operation.

CONCLUSIONS

At the outset I found it necessary to use the spinocain without drugs which would mask its action. It was a time of inevitable anxiety, owing to my disquieting experiences with spinal injections of simple novocain. Anaesthesia was easily obtained in the early cases, and as several of them were poor surgical risks with advanced cancer I felt hopeful. Then, for a time, I found it less easy to puncture the theca, and other drawbacks connected with the method assumed importance. One became unpleasantly aware that the patient was "alive" to his surroundings, and that spinal anaesthesia might be marred by cerebral hyperaesthesia. Success depends on eliminating harmful environmental factors. Every patient needs some adjuvant according to his, or her, mental make-up. It seems that mere *coaxing* for the puncture, and diverting chatter during the operation, will be enough for some.

Granted, however, good psychanaesthesia, obtained by appropriate means, I am sure that the anaesthetist who is familiar with the spinal route to surgical anaesthesia in suitable cases will earn the thanks of both patient and surgeon. The following are my reasons for this opinion;

they are based on the 250 consecutive cases of the last eighteen months:

1. A perfect and safe surgical anaesthesia is obtainable in about 88 to 98 per cent. of operations in the abdomen and legs. The lower figure occurs with the higher levels of anaesthesia.

2. Anaesthesia is not derived from the introduction of narcotics into, and the altered chemistry of, the blood, but merely by the transitory interruption of conductivity in the nerves of the lower part of the body.

3. The apparatus is simple and can be carried in the pocket.

4. The dose, except in childhood, is standardized, and varies only with the level of anaesthesia desired. This makes for ease and safety, and is an advantage over other anaesthetics.

5. The metabolic processes of the body are reduced during the operation for one to one and a half hours, thus conserving energy. With recovery from paralysis, the rested heart, vessels, muscles, and glandular organs are found working with notable buoyancy and renewed strength.

6. The patient's muscles relax completely, as if aiding, rather than resisting, the surgeon's manœuvres. Undisturbed tranquillity reigns in the field of operation, and smooth, easy working results, which saves the strength of both patient and surgeon, and minimizes the trauma to tissues.

7. The paralysis of inhibitory sympathetic nerves to the intestine assists by encouraging peristalsis and bowel clearance in cases of intestinal obstruction; indeed, spinal anaesthesia is used as a treatment for paralytic ileus.

8. The patient is returned to the ward conscious and quiet. No recovery restlessness ensues. So are spared his stitched and wounded tissues, his recuperative powers, and the time and energy of the nursing staff. Food is taken early, and the body tissues are ready to digest and to use it.

9. Infants, children, and adults, in many cases, prefer it.

This paper would not be complete without grateful acknowledgement to all the kind and patient colleagues who have helped me through the difficulties of the early stages of this research.

TREATMENT OF DISSEMINATED SCLEROSIS BY LIVER

BY

ALEXANDER GOODALL, M.D., F.R.C.P.ED.
PHYSICIAN IN ORDINARY, ROYAL INFIRMARY, EDINBURGH

AND

JAMES K. SLATER, M.B., F.R.C.P.ED.
ASSISTANT PHYSICIAN, ROYAL INFIRMARY, EDINBURGH

It has been shown by Ungley and Suzman[1] and others that treatment by liver is followed by a remarkable improvement in the combined degeneration of the spinal cord associated with pernicious anaemia. It occurred to us that other affections of the nervous system might be benefited by similar means.

In pernicious anaemia there is no relationship between the degree of blood defect and the severity of the nerve affection, and either may appear before or without the other. The nerve symptoms are not a consequence of the anaemia, but may be the result of the same or a concomitant deficiency in a hormone or vitamin. The latter view is suggested by Mellanby,[2] who considers that the anaemia is benefited by a water-soluble factor, while experimental nerve lesions have been cured by a fat-soluble factor. On these grounds we began the treatment of cases of disseminated sclerosis with liver. So far only whole liver, lightly cooked, has been employed, and patients have been advised to consume half a pound daily. There is not the difficulty in connexion with digestive disturbance which so often occurs in pernicious anaemia. We have not yet employed liver extract or preparations of stomach. Our observations extend over a period of seven months only, but the results already obtained seem to us to justify the publication of abridged notes of our first five cases. These cases are consecutive. We hope to extend the list with several later cases now under treatment.

CASE I.

F., farm worker, recommended by Dr. McWhir, Norham, was admitted on July 15th, 1930. She complained of numbness of the feet, thighs, and abdomen, with weakness and nervousness.

History.—Family history and home surroundings were satisfactory. No previous illness of importance. Present illness began in June, 1930, with numbness in the toes, which gradually spread to the legs, thighs, and abdomen as far as the umbilicus. About the same time patient noticed weakness and unsteadiness in walking, which became so severe that she had to give up work on June 26th.

Examination.—There was intention tremor, and patient could not be trusted to handle glass or chinaware. There was lateral nystagmus, and the temporal side of the right disc was pathologically pale. There was slight Rombergism. Both plantar reflexes were extensor. The knee-jerks were increased. The abdominal reflexes were absent. There was no anaemia, and the Wassermann reaction in blood and cerebro-spinal fluid was negative.

Progress.—On July 26th the administration of half a pound of liver daily was begun. On August 11th patient said that she was feeling better, and went home promising to continue the treatment. In November Dr. McWhir had occasion to telephone us, and mentioned incidentally that the girl was better, and had returned to work. On April 9th, 1931, patient reported that she had been taking half a pound of liver daily for the first three months, and thereafter she had gradually reduced the amount, until for the past two weeks she had been taking only half a pound a week. Nystagmus was difficult to elicit. Intention tremor was absent. Abdominal reflexes present on right side, but absent on left. There was no numbness in the legs, and the gait was normal. Plantar responses were now flexor. The girl appeared to be in robust health, and said that she was feeling perfectly fit.

CASE II

M., aged 25, hosiery mechanic, was admitted on the recommendation of Dr. Norman Smith on September 15th, 1930. He complained of numbness of the fingers, diplopia, weakness, and stiffness of the legs.

History.—There had been numbness for over two years. Diplopia had occurred from time to time. The legs had become weaker, and sometimes dragged. Patient had been unable to work for eighteen months.

Examination.—The patient was a tall, well-nourished man. There was no interference with sensation. There was lateral nystagmus. Pupil reactions and both fundi were normal. There was diplopia on looking to the right. There was no wasting of muscles. The gait was remarkable. The right leg tended to drag, so that the toes often scraped along the ground. At other times the legs showed great spasticity. There was a tremor on holding out the hands, which greatly increased when fine movements were attempted. There was some difficulty in starting micturition. The knee-jerks were increased. The plantar reflexes were extensor. The abdominal reflexes could not be elicited. The Wassermann reaction was negative in blood and cerebro-spinal fluid. Other systems presented nothing of note.

Progress.—Patient was discharged *in statu quo*, and for some time thereafter received weekly doses of tryparsamide without benefit. On January 9th, 1931, he was definitely worse, and, aided by two sticks, walked with great difficulty. On that date liver treatment was begun. Patient reported on March 25th. He stated that he was immensely better, and that he had been working four hours a day for over a month.

On examination it was found that the patient could walk briskly, but that there was still some muscular weakness and a tendency of the right foot to drag. The sensation of numbness had disappeared. Nystagmus was less. There was no diplopia. The plantar reflexes were flexor. The abdominal reflexes were absent.

CASE III

F., aged 23, was referred to one of us on January 9th, 1931, by Dr. Ramsay of Fauldhouse, who wrote: "A week before Christmas she had an attack of mild influenza and complained of stiffness in her legs and a gripping sensation round her waist. Her legs have improved, but this sensation in the waist persists. I noticed that her legs rather dragged. Her appearance, gait, and reflexes suggested an early disseminated sclerosis." We elicited the further information that there was a sensation of pricking in the fingers, aggravated by washing or any friction. The patient had been a keen hockey player, but had felt unable to play for over two years, and she found that refereeing a match—part of her duty as a school teacher—was almost beyond her powers.

Examination.—No anaemia or circulatory disturbance was found. There was no tremor. There was slight nystagmus. Pupil reactions were normal. No change was seen in either fundus. The knee-jerks were increased, with slight clonus. No ankle-clonus. Plantar response was flexor, and difficult to elicit. The abdominal reflexes were absent. Patient was advised to eat half a pound of lightly cooked liver daily.

Progress.—She was seen again on February 14th. Improvement was obvious, and the patient was delighted with her ability to resume games. There was still a sensation of pins and needles. Nystagmus was just noticeable, and only on looking to the left. Knee-jerks were still increased. Abdominal reflexes absent. Patient again reported on April 5th. She stated that she was now in a position to tire her pupils at games, and that she was gaining weight. Her only complaints were that she disliked washing, as it caused pins and needles, and that there was sometimes a feeling of weakness round the waist. Nystagmus could not be elicited. The knee-jerks were no longer increased. Abdominal reflexes were absent.

CASE IV

Mrs. K., aged 34, recommended by Dr. Norman Smith.

History.—Following the birth of a child six years ago, patient noticed that her legs became easily tired after walking. About the same time she experienced a sensation of numbness in the right arm, particularly in the hand and fingers. Difficulty in walking gradually increased until she could walk only with the aid of a stick, and two years ago both legs became numb from the knees downwards. The numbness in the legs varied considerably, but was always present to a greater or less extent. A relation drew attention to a stuttering in patient's speech eighteen months ago, and this difficulty slowly became more marked: Except for short intervals there has been urgency in micturition. Since the beginning of the illness patient has become increasingly nervous and tremulous. There have been no eye symptoms.

Examination.—On September 28th, 1930, both optic discs were healthy. There was a fine lateral nystagmus in both eyes. Intention tremor was present on the right side, but absent on the left. The muscular power was good in both arms, but the tendon reflexes were definitely brisk. On the right side the abdominal reflex was just present, but on the left it was absent. Both legs were spastic, the right more so than the left. Knee- and ankle-clonus were present on both sides, and there was a double extensor response. Superficial sensation was everywhere unimpaired, and joint sense was normal. Vibration sense was absent in the right leg, and definitely diminished in the left. Co-ordination in the legs was normal. The blood Wassermann reaction was negative. Patient had courses of Fowler's solution without improvement, and was then given a pill containing zinc oxide and iodoform, to be taken three times daily; a course of graduated exercises was suggested.
